

TI SYS/BIOS Real-time Operating System v6.x User's Guide

Literature Number: SPRUEX3F
August 2010

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.

About This Manual

This manual describes the TI SYS/BIOS Real-time Operating System, which is also called "SYS/BIOS". The latest version number as of the publication of this manual is SYS/BIOS 6.21. Previous versions of SYS/BIOS were called DSP/BIOS. The new name reflects that this operating system can also be use on processors other than DSPs.

SYS/BIOS gives developers of mainstream applications on Texas Instruments devices the ability to develop embedded real-time software. SYS/BIOS provides a small firmware real-time library and easy-to-use tools for real-time tracing and analysis.

Notational Conventions

This document uses the following conventions:

- ❑ Program listings, program examples, and interactive displays are shown in a special typeface. Examples use a bold version of the special typeface for emphasis.

Here is a sample program listing:

```
#include <xdc/runtime/System.h>

int main(){
    System_printf("Hello World!\n");
    return (0);
}
```

- ❑ Square brackets ([and]) identify an optional parameter. If you use an optional parameter, you specify the information within the brackets. Unless the square brackets are in a **bold** typeface, do not enter the brackets themselves.

About SYS/BIOS

This chapter provides an overview of SYS/BIOS and describes its relationship to XDCtools.

Topic	Page
1.1 What is SYS/BIOS?	1-2
1.2 What's New?	1-3
1.3 How are SYS/BIOS, RTSC, and XDCtools Related?	1-4
1.4 How are SYS/BIOS and IPC related?	1-8
1.5 SYS/BIOS Packages	1-9
1.6 For More Information	1-10

1.1 What is SYS/BIOS?

SYS/BIOS is a scalable real-time kernel. It is designed to be used by applications that require real-time scheduling and synchronization or real-time instrumentation. SYS/BIOS provides preemptive multi-threading, hardware abstraction, real-time analysis, and configuration tools. SYS/BIOS is designed to minimize memory and CPU requirements on the target.

SYS/BIOS provides the following benefits:

- ❑ All SYS/BIOS objects can be configured statically or dynamically.
- ❑ To minimize memory size, the APIs are modularized so that only those APIs that are used by the program need to be bound into the executable program. In addition, statically-configured objects reduce code size by eliminating the need to include object creation calls.
- ❑ Error checking and debug instrumentation is configurable and can be completely removed from production code versions to maximize performance and minimize memory size.
- ❑ Almost all system calls provide deterministic performance to enable applications to reliably meet real-time deadlines.
- ❑ To improve performance, instrumentation data (such as logs and traces) is formatted on the host.
- ❑ The threading model provides thread types for a variety of situations. Hardware interrupts, software interrupts, tasks, idle functions, and periodic functions are all supported. You can control the priorities and blocking characteristics of threads through your choice of thread types.
- ❑ Structures to support communication and synchronization between threads are provided. These include semaphores, mailboxes, events, gates, and variable-length messaging.
- ❑ Dynamic memory management services offering both variable-sized and fixed-sized block allocation.
- ❑ An interrupt dispatcher handles low-level context save/restore operations and enables interrupt service routines to be written entirely in C.
- ❑ System services support the enabling/disabling of interrupts and the plugging of interrupt vectors, including multiplexing interrupt vectors onto multiple sources.

1.2 What's New?

This book describes SYS/BIOS 6, a major new release that introduces significant changes. If you have used previous versions of SYS/BIOS, you will encounter these major changes to basic functionality:

- ❑ The name DSP/BIOS has been changed to SYS/BIOS to reflect the fact that it can be used on processors other than DSPs.
- ❑ SYS/BIOS uses a new configuration technology based on the Real-Time Software Components (RTSC) technology. For more information, see Section 1.3 of this book and the RTSC-Pedia wiki at <http://rtsc.eclipse.org/docs-tip>.
- ❑ The APIs have changed. A compatibility layer ensures that DSP/BIOS 5.4x or earlier applications will work unmodified. However, note that the PIP module is no longer supported. For details, see the *Migrating a DSP/BIOS 5 Application to SYS/BIOS 6 (SPRAAS7A)* application note.
- ❑ The SYS/BIOS RTA tools are Eclipse Plug-ins, which work in Code Composer Studio (CCS) v4. Support for CCSv3.x is no longer provided.

In addition, significant enhancements have been made in the areas that include the following:

- ❑ Up to 32 priority levels are available for both tasks and software interrupt (Swi) threads.
- ❑ A new timer module is provided that enables applications to configure and use timers directly rather than have time-driven events limited to using the system tick.
- ❑ All kernel objects may be created statically or dynamically.
- ❑ An additional heap manager, called HeapMultiBuf, enables fast, deterministic variable-sized memory allocation performance that does not degrade regardless of memory fragmentation.
- ❑ A more flexible memory manager supports the use of multiple, concurrent heaps and enables developers to easily add custom heaps.
- ❑ A new Event object enables tasks to pend on multiple events, including semaphores, mailboxes, message queues, and user-defined events.
- ❑ An additional Gate object supports priority inheritance.
- ❑ Hook functions are supported for hardware and software interrupt objects as well as tasks.
- ❑ An option is provided to build the operating system with parameter checking APIs that assert if invalid parameter values are passed to a system call.

- ❑ A standardized method allows SYS/BIOS APIs to handle errors, based on an error block approach. This enables errors to be handled efficiently without requiring the application to catch return codes. In addition, you can easily have the application halted whenever a SYS/BIOS error occurs, because all errors now pass through a single handler.
- ❑ The system log and execution graph in the Real-Time Analysis (RTA) tools support both dynamically and statically-created tasks.
- ❑ More powerful logging functions include a timestamp, up to 6 words per log entry, and the ability for logging events to span more than one log if additional storage is required.
- ❑ Per-task CPU load is now supported in addition to total CPU load.
- ❑ Host-native execution is provided. This enables developers to create prototype SYS/BIOS applications using Windows developer tools such as Visual C++, without the need for a DSP board or simulator. See Appendix A for details.

1.3 How are SYS/BIOS, RTSC, and XDCtools Related?

Developing real-time applications using SYS/BIOS 6 requires not only the real-time operating system (RTOS) libraries and tools themselves, but also technology delivered through the use of Real Time Software Components (RTSC). This section contains a brief introduction to using RTSC with SYS/BIOS. However, we recommend that you read the detailed documentation about RTSC that's contained on the RTSC-pedia web site at http://rtsc.eclipse.org/docs-tip/Main_Page.

RTSC itself is an open-source project within the Eclipse.org ecosystem for providing reusable software components (called "packages") for use in embedded systems. XDCtools is the actual product that contains all of the tools necessary for you to use the SYS/BIOS components and configure your application. RTSC and XDCtools are important to SYS/BIOS users because:

- ❑ SYS/BIOS is delivered as a set of RTSC packages that provide the modules that make up the RTOS. See Section 1.3.1.
- ❑ RTSC provides the technology that users use to configure which RTOS modules are included in the ultimate run-time image as well as create static instances of RTOS objects such as tasks and semaphores for the applications. See Section 1.3.2.
- ❑ RTSC provides critical run-time APIs that SYS/BIOS and its users leverage, such as memory allocation, logging, and system control. See Section 1.3.3.

The subsections that follow give an overview of these three aspects of using RTSC with SYS/BIOS.

1.3.1 SYS/BIOS as a Set of RTSC Packages

SYS/BIOS is implemented as a set of RTSC packages, each of which delivers a subset of the product's functionality. The RTSC standard recommends a naming convention for packages to aid readability and to ensure that packages delivered from different sources don't have namespace collisions that will pose problems for the system integrator. If you are familiar with the Java package naming convention, you will find it to be quite similar.

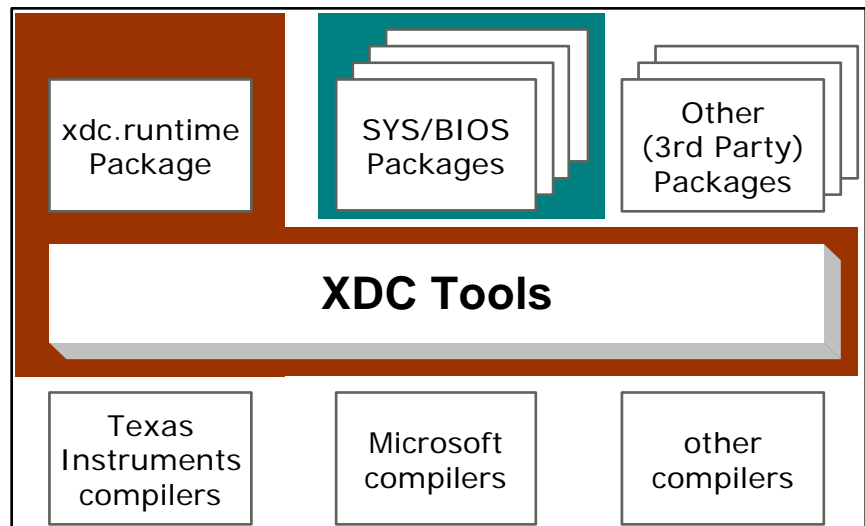

SYS/BIOS packages conform to this convention with names that consist of a hierarchical naming pattern; each level is separated by a period ("."). Usually, the highest level of the name is the vendor ("ti"), followed by the product ("sysbios"), and then followed by the module and submodule names (for example, "knl").

These names have the added benefit of reflecting the physical layout of the package within the file system where SYS/BIOS has been installed. For example, the ti.sysbios.knl package files can be found at

```
BIOS_INSTALL_DIR\bios_6_3#_##\packages\ti\sysbios\knl
```

See Section 1.5 for a partial list of the packages delivered by SYS/BIOS.

You can picture the architecture of the tools used to create applications as shown in the following figure:

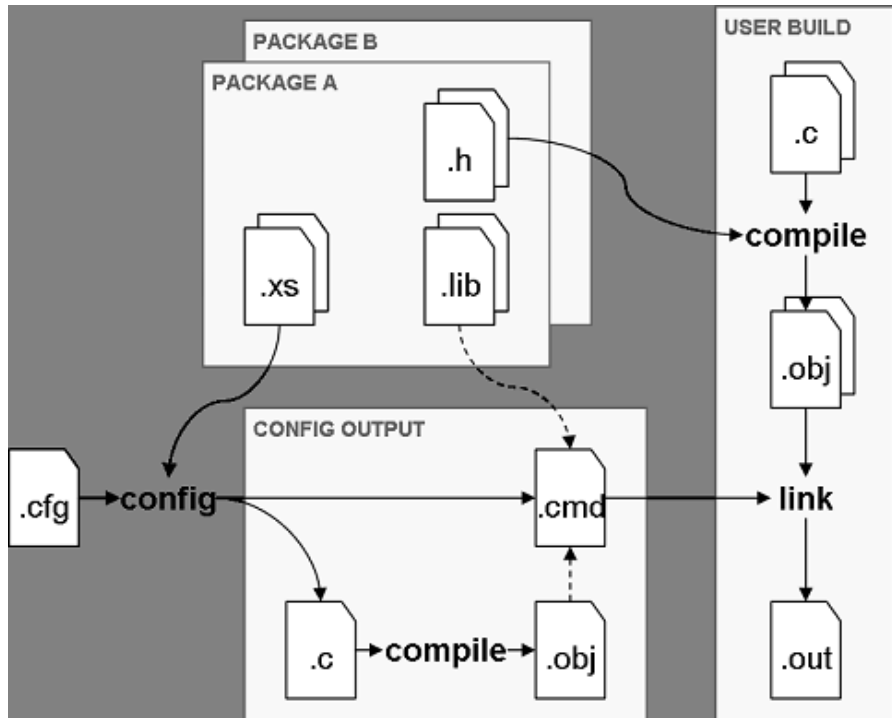

This book describes the SYS/BIOS packages. The RTSC-pedia web site describes the components with the red background (XDCtools and the xdc.runtime package).

1.3.2 Configuring SYS/BIOS Using RTSC

Configuration is an essential part of using SYS/BIOS and is used for the following purposes:

- ❑ It specifies the modules and packages that will be used and the objects to statically create.
- ❑ It performs integrity checks between specified and dependent packages to make sure that they are compatible for integration.
- ❑ It sets configuration variables (i.e., options) for modules and objects to change their default run-time behavior.

An application's configuration is expressed within one or more textual script (.cfg) files which are parsed by the RTSC configuration tool to generate corresponding C source code, C header, and linker command files that can be compiled/linked into the end application. The following diagram depicts a build flow for a typical SYS/BIOS application.

The configuration .cfg file uses simple JavaScript syntax to set properties and call methods provided by objects. The combination of JavaScript and the script objects provided by XDCtools is referred to as an XDCscript.

Users can create and modify their applications' configuration files in two different ways: by writing the textual .cfg file directly, or by using the visual configuration tool (XGCONF) embedded in Code Composer Studio.

The following figure shows the XGCONF configuration tool in Code Composer Studio being used to configure a static SYS/BIOS Task instance. You can see this configuration for yourself in the "Static Example" SYS/BIOS project template in CCS. See the *SYS/BIOS Getting Started Guide* for instructions on building a SYS/BIOS project in Code Composer Studio.

The screenshot shows the XGCONF configuration tool in Code Composer Studio. The main window displays the configuration for 'instance task0'. The 'Params' tab is active, showing a table of parameters. The 'Outline' window on the right shows a tree view of the configuration hierarchy, with 'task0' selected under 'ti.sysbios.knl.Task'.

Name	Value	Summary
Create Args		
fxn	task0Fxn	
Params		
arg0	1	Task function argument. Defa...
arg1	2	Task function argument. Defa...
priority	15	Task priority (0 to numPrioritie...
stack	null	Task stack pointer. Default = n...
stackSize	1024	Task stack size in MAUs. The ...
stackSection		Mem section used for staticall...
stackHeap	null	Mem heap used for dynamical...
env	null	Environment data struct
vitalTaskFlag	true	Exit system immediately when ...

The instance of a Task (named "task0") that was set up in the configuration tool will cause the application's textual configuration file to be generated with the proper syntax so that this static object is created. The corresponding XDCscript code that is created for task0 looks something like:

```
var Task = xdc.useModule('ti.sysbios.knl.Task');
Task.numPriorities = 16;
Task.idleTaskStackSize = 1024;
var tskParams = new Task.Params;
tskParams.arg0 = 1;
tskParams.arg1 = 2;
tskParams.priority = 15;
tskParams.stack = null;
tskParams.stackSize = 1024;
var task0 = Task.create('&task0Fxn', tskParams);
```

1.3.3 RTSC Run-Time APIs

The XDC run-time package (`xdc.runtime`) contains a number of different modules that allow it to provide basic system services that your SYS/BIOS application will need to operate successfully. By default, all SYS/BIOS applications automatically add the `xdc.runtime` package during build time.

The functionality provided by the `xdc.runtime` package can be roughly partitioned into four categories:

Category	Modules	Description
System Services	System	Basic low-level "system" services. For example, character output, printf-like output, and exit handling.
	Startup	Allows functions defined by different modules to be run before <code>main()</code> .
Memory Management	Memory	Creates/frees memory heaps statically or dynamically.
Real-Time Diagnostics	Log	Allows events to be logged by RTSC modules and the application, and then passes those events to a Log handler.
	Assert	Provides for configurable assertion diagnostics.
	Error	Allows raising, checking, and handling errors defined by any modules.
	Timestamp	Provides time-stamping APIs that forward calls to a platform-specific time stamper (or one provided by CCS).
	Diags	Allows diagnostics to be enabled/disabled at either configuration- or run-time on a per-module basis.
Concurrency Support	Gate	Protects against concurrent access to critical data structures.

1.4 How are SYS/BIOS and IPC related?

SYS/BIOS is used by the Inter-Process Communication (IPC) APIs, which are described in the *SYS/BIOS Inter-Processor Communication (IPC) and I/O User's Guide* (SPRUGO6). Those APIs provide for communication between processors in a multi-processor environment and communication to peripherals. IPC is designed for use on processors running SYS/BIOS applications.

Several examples in this book use the `ti.sdo.utils.List` module, which is provided as part of the IPC distribution.

1.5 SYS/BIOS Packages

SYS/BIOS provides the following packages:

Table 1–1 Packages and Modules Provides by SYS/BIOS

Package	Description
ti.sysbios.benchmark	Contains specifications for benchmark tests. Provides no modules, APIs, or configuration. See Appendix C.
ti.sysbios.family.*	Contains specifications for target/device-specific functions.
ti.sysbios.gates	Contains several implementations of the IGateProvider interface for use in various situations. These include GateHwi, GateSwi, GateTask, GateMutex, and GateMutexPri. See Section 3.3.
ti.sysbios.genx	Provides a command-line tool to build example applications.
ti.sysbios.hal	Contains Hwi, Timer, and Cache modules. See Section 6.2, Section 6.3, and Section 6.4.
ti.sysbios.heaps	Provides several implementations of the XDCtools IHeap interface. These include HeapBuf (fixed-size buffers), HeapMem (variable-sized buffers), and HeapMultiBuf (multiple fixed-size buffers). See Chapter 5.
ti.sysbios.interfaces	Contains interfaces for modules to be implemented, for example, on a device or platform basis.
ti.sysbios.knl	Contains modules for the SYS/BIOS kernel, including Swi, Task, Idle, and Clock. See Chapter 2 and Chapter 4. Also contains modules related to inter-process communication: Event, Mailbox, and Semaphore. See Chapter 3.
ti.sysbios.utils	Contains Load module, which provides global CPU load as well as thread-specific load.

1.6 For More Information

You can read the following additional documents to learn more about SYS/BIOS and XDCtools:

- ❑ *XDCtools Release Notes* (in XDC_INSTALL_DIR). Includes information about software version, upgrades and compatibility, host and target device support, validation, and known issues.
- ❑ *SYS/BIOS Release Notes* (BIOS_INSTALL_DIR/release_notes.html). Includes information about changes in each version, known issues, validation, and device support.
- ❑ *SYS/BIOS Getting Started Guide* (BIOS_INSTALL_DIR/docs/Bios_Getting_Started_Guide.doc). Includes steps for installing and validating the installation.
- ❑ *Migrating a DSP/BIOS 5 Application to SYS/BIOS 6* (SPRAAS7A). (BIOS_INSTALL_DIR/docs/Bios_Legacy_App_Note.pdf)
- ❑ RTSC-pedia wiki: <http://rtsc.eclipse.org/docs-tip>
- ❑ Code Composer Studio Mediawiki: <http://tiexpressdsp.com/wiki/index.php?title=CCSv4>
- ❑ CCSv4 online help contains reference information about XDCtools and SYS/BIOS packages and their modules, APIs, XDCtools configuration, data structures, etc. See Section 1.6.1.

1.6.1 Using the API Reference Help System

To open the online help for SYS/BIOS, you can choose **SYS/BIOS API Documentation** from the **Texas Instruments > SYS/BIOS** group in the Windows **Start** menu.

To open online help for XDCtools, you can choose **XDCtools Documentation** from the **Texas Instruments > XDCtools** group in the Windows **Start** menu.

You can also open help for CCSv4, SYS/BIOS, and XDCtools together from within CCSv4.

To see the SYS/BIOS API documentation, you must have included your SYS/BIOS installation directory path in the XDCPATH environment variable. Please refer to the *XDCtools Getting Started Guide* for details on how to do this.

Click "+" next to a repository to expand its list of packages. Click "+" next to a package name to see the list of modules it provides. You can further expand the tree to see a list of the functions provided by a module. Double-click on a package or module to see its reference information.

The SYS/BIOS API documentation is under the "sysbios" package. To view API documentation on memory allocation, logs, timestamps, asserts, and system, expand the "xdc.runtime" package. The "bios" package contains only the compatibility modules for earlier versions of SYS/BIOS.

Notice the following icons in this window:

Busy displaying the requested page.

Close all page tabs.

For each topic you view, there is a tab across the top of the page area. You can use these to quickly return to other pages you have viewed. You can also use the arrows next to "Views" to move backward and forward in your history of page views.

To close a page and remove its tab, click the X on the tab.

The xs option '--xp' adds the SYS/BIOS 6.0 packages to the path searched for XDCtools packages. If you have added this directory to your XDCPATH environment variable definition as described in the *SYS/BIOS 6 Getting Started Guide*, you do not need to use the --xp command-line option.

Threading Modules

This chapter describes the types of threads a SYS/BIOS program can use.

Topic	Page
2.1 SYS/BIOS Startup Sequence	2-2
2.2 Overview of Threading Modules	2-4
2.3 Hardware Interrupts	2-15
2.4 Software Interrupts	2-24
2.5 Tasks	2-44
2.6 The Idle Loop	2-64
2.7 Example Using Hwi, Swi, and Task Threads	2-65

2.1 SYS/BIOS Startup Sequence

The SYS/BIOS startup sequence is logically divided into two phases—those operations that occur prior to the application's "main()" function being called and those operations that are performed after the application's "main()" function is invoked. Control points are provided at various places in each of the two startup sequences for user startup functions to be inserted.

The "before main()" startup sequence is governed completely by the XDCtools runtime package. For more information about the boot sequence prior to main, refer to the "XDCtools Boot Sequence and Control Points" section in the *XDCtools Consumer User's Guide*.

The "after main()" startup sequence is governed by SYS/BIOS and is initiated by an explicit call to the BIOS_start() function at the end of the application's main() function.

The XDCtools runtime startup sequence is as follows:

- 1) Immediately after CPU reset, perform target/device-specific CPU initialization (beginning at c_int00).
- 2) Prior to cinit(), run the single user-supplied "reset function" (the xdc.runtime.Startup module provides this hook).
- 3) Run cinit() to initialize C runtime environment.
- 4) Run the user-supplied "first functions" (the xdc.runtime.Startup module provides this hook).
- 5) Run all the module initialization functions.
- 6) Run pinit().
- 7) Run the user-supplied "last functions" (the xdc.runtime.Startup module provides this hook).
- 8) Run main().

The SYS/BIOS startup sequence begins at the end of main() when BIOS_start() is called:

- 1) **Startup Functions.** Run the user-supplied "startup functions" (see BIOS.startupFxns).
- 2) **Enable Hardware Interrupts.**
- 3) **Enable Software Interrupts.** If the system supports software interrupts (Swis) (see BIOS.swiEnabled), then the SYS/BIOS startup sequence enables Swis at this point.

- 4) **Timer Startup.** If the system supports Timers, then at this point all configured timers are initialized per their user-configuration. If a timer was configured to start "automatically", it is started here.
- 5) **Task Startup.** If the system supports Tasks (see BIOS.taskEnabled), then task scheduling begins here. If there are no statically or dynamically created Tasks in the system, then execution proceeds directly to the idle loop.

The following configuration script excerpt installs a user-supplied startup function at every possible control point in the RTSC and SYS/BIOS startup sequence. Configuration scripts have the filename extension ".cfg" and are written in the XDCscript language, which is used to configure RTSC modules.

```
/* get handle to xdc Startup module */
var Startup = xdc.useModule('xdc.runtime.Startup');

/* install "reset function" */
Startup.resetFxn = '&myReset';

/* install a "first function" */
var len = Startup.firstFxn.length
Startup.firstFxn.length++;
Startup.firstFxn[len] = '&myFirst';

/* install a "last function" */
var len = Startup.lastFxn.length
Startup.lastFxn.length++;
Startup.lastFxn[len] = '&myLast';

/* get handle to BIOS module */
var BIOS = xdc.useModule('ti.sysbios.BIOS');

/* install a BIOS startup function */
BIOS.addUserStartupFunction('&myBiosStartup');
```

2.2 Overview of Threading Modules

Many real-time applications must perform a number of seemingly unrelated functions at the same time, often in response to external events such as the availability of data or the presence of a control signal. Both the functions performed and when they are performed are important.

These functions are called threads. Different systems define threads either narrowly or broadly. Within SYS/BIOS, the term is defined broadly to include any independent stream of instructions executed by the processor. A thread is a single point of control that can activate a function call or an interrupt service routine (ISR).

SYS/BIOS enables your applications to be structured as a collection of threads, each of which carries out a modularized function. Multithreaded programs run on a single processor by allowing higher-priority threads to preempt lower-priority threads and by allowing various types of interaction between threads, including blocking, communication, and synchronization.

Real-time application programs organized in such a modular fashion—as opposed to a single, centralized polling loop, for example—are easier to design, implement, and maintain.

SYS/BIOS provides support for several types of program threads with different priorities. Each thread type has different execution and preemption characteristics. The thread types (from highest to lowest priority) are:

- ❑ **Hardware interrupts (Hwi)**, which includes Timer functions
- ❑ **Software interrupts (Swi)**, which includes Clock functions
- ❑ **Tasks (Task)**
- ❑ **Background thread (Idle)**

These thread types are described briefly in the following section and discussed in more detail in the rest of this chapter.

2.2.1 Types of Threads

The four major types of threads in a SYS/BIOS program are:

- ❑ **Hardware interrupt (Hwi) threads.** Hwi threads (also called Interrupt Service Routines or ISRs) are the threads with the highest priority in a SYS/BIOS application. Hwi threads are used to perform time critical tasks that are subject to hard deadlines. They are triggered in response to external asynchronous events (interrupts) that occur in the real-time environment. Hwi threads always run to completion but can be preempted temporarily by Hwi threads triggered by other interrupts, if enabled. See Section 2.3, *Hardware Interrupts*, page 2-15, for details about hardware interrupts.

- ❑ **Software interrupt (Swi) threads.** Patterned after hardware interrupts (Hwi), software interrupt threads provide additional priority levels between Hwi threads and Task threads. Unlike Hwis, which are triggered by hardware interrupts, Swis are triggered programmatically by calling certain Swi module APIs. Swis handle threads subject to time constraints that preclude them from being run as tasks, but whose deadlines are not as severe as those of hardware ISRs. Like Hwi's, Swi's threads always run to completion. Swis allow Hwis to defer less critical processing to a lower-priority thread, minimizing the time the CPU spends inside an interrupt service routine, where other Hwis can be disabled. Swis require only enough space to save the context for each Swi interrupt priority level, while Tasks use a separate stack for each thread. See Section 2.4, *Software Interrupts*, page 2-24, for details about Swis.
- ❑ **Task (Task) threads.** Task threads have higher priority than the background (Idle) thread and lower priority than software interrupts. Tasks differ from software interrupts in that they can wait (block) during execution until necessary resources are available. Tasks require a separate stack for each thread. SYS/BIOS provides a number of mechanisms that can be used for inter-task communication and synchronization. These include Semaphores, Events, Message queues, and Mailboxes. See Section 2.5, *Tasks*, page 2-44, for details about tasks.
- ❑ **Idle Loop (Idle) thread.** Idle threads execute at the lowest priority in a SYS/BIOS application and are executed one after another in a continuous loop (the Idle Loop). After main returns, a SYS/BIOS application calls the startup routine for each SYS/BIOS module and then falls into the Idle Loop. Each thread must wait for all others to finish executing before it is called again. The Idle Loop runs continuously except when it is preempted by higher-priority threads. Only functions that do not have hard deadlines should be executed in the Idle Loop. See Section 2.6, *The Idle Loop*, page 2-64, for details about the background thread.

Another type of thread, a Clock thread, is run within the context of a Swi thread that is triggered by a Hwi thread invoked by a repetitive timer peripheral interrupt. See Section 4.2 for details.

2.2.2 Choosing Which Types of Threads to Use

The type and priority level you choose for each thread in an application program has an impact on whether the threads are scheduled on time and executed correctly. SYS/BIOS static configuration makes it easy to change a thread from one type to another.

A program can use multiple types of threads. Here are some rules for deciding which type of object to use for each thread to be performed by a program.

- ❑ **Swi or Task versus Hwi.** Perform only critical processing within hardware interrupt service routines. Hwis should be considered for processing hardware interrupts (IRQs) with deadlines down to the 5-microsecond range, especially when data may be overwritten if the deadline is not met. Swis or Tasks should be considered for events with longer deadlines—around 100 microseconds or more. Your Hwi functions should post Swis or tasks to perform lower-priority processing. Using lower-priority threads minimizes the length of time interrupts are disabled (interrupt latency), allowing other hardware interrupts to occur.
- ❑ **Swi versus Task.** Use Swis if functions have relatively simple interdependencies and data sharing requirements. Use tasks if the requirements are more complex. While higher-priority threads can preempt lower priority threads, only tasks can wait for another event, such as resource availability. Tasks also have more options than Swis when using shared data. All input needed by a Swi's function should be ready when the program posts the Swi. The Swi object's trigger structure provides a way to determine when resources are available. Swis are more memory-efficient because they all run from a single stack.
- ❑ **Idle.** Create Idle threads to perform noncritical housekeeping tasks when no other processing is necessary. Idle threads typically have no hard deadlines. Instead, they run when the system has unused processor time. Idle threads run sequentially at the same priority. You may use Idle threads to reduce power needs when other processing is not being performed. In this case, you should not depend upon housekeeping tasks to occur during power reduction times.
- ❑ **Clock.** Use Clock functions when you want a function to run at a rate based on a multiple of the interrupt rate of the peripheral that is driving the Clock tick. Clock functions can be configured to execute either periodically or just once. These functions run as Swi functions.
- ❑ **Clock versus Swi.** All Clock functions run at the same Swi priority, so one Clock function cannot preempt another. However, Clock functions can post lower-priority Swi threads for lengthy processing. This ensures that the Clock Swi can preempt those functions when the next system tick occurs and when the Clock Swi is posted again.

- ❑ **Timer.** Timer threads are run within the context of a Hwi thread. As such, they inherit the priority of the corresponding Timer interrupt. They are invoked at the rate of the programmed Timer period. Timer threads should do the absolute minimum necessary to complete the task required. If more processing time is required, consider posting a Swi to do the work or posting a Semaphore for later processing by a task so that CPU time is efficiently managed.

2.2.3 A Comparison of Thread Characteristics

Table 2-1 provides a comparison of the thread types supported by SYS/BIOS.

Table 2-1. Comparison of Thread Characteristics

Characteristic	Hwi	Swi	Task	Idle
Priority	Highest	2nd highest	2nd lowest	Lowest
Number of priority levels	family/device-specific	Up to 32 (16 for MSP430 and C28x). Periodic functions run at the priority of the Clock Swi.	Up to 32 (16 for MSP430 and C28x). This includes 1 for the Idle Loop.	1
Can yield and pend	No, runs to completion except for preemption	No, runs to completion except for preemption	Yes	Should not pend. Pending would disable all registered Idle threads.
Execution states	Inactive, ready, running	Inactive, ready, running	Ready, running, blocked, terminated	Ready, running
Thread scheduler disabled by	Hwi_disable()	Swi_disable()	Task_disable()	Program exit
Posted or made ready to run by	Interrupt occurs	Swi_post(), Swi_andn(), Swi_dec(), Swi_inc(), Swi_or()	Task_create() and various task synchronization mechanisms (Event, Semaphore, Mailbox)	main() exits and no other thread is currently running
Stack used	System stack (1 per program)	System stack (1 per program)	Task stack (1 per task)	Task stack used by default (see Note 1)

Notes: 1) If you disable the Task Manager, Idle threads use the system stack.

Table 2.1. Comparison of Thread Characteristics (continued)

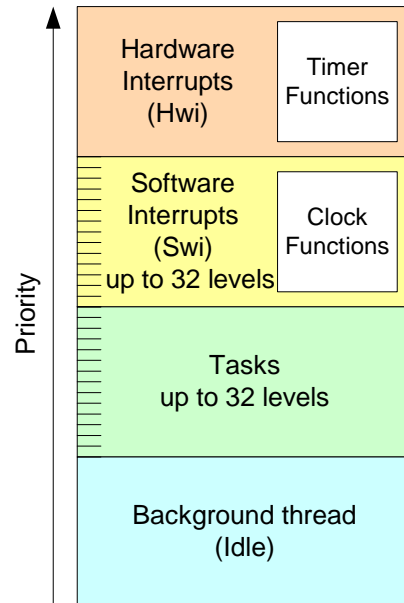

Characteristic	Hwi	Swi	Task	Idle
Context saved when preempts other thread	Entire context minus saved-by-callee registers (as defined by the TI C compiler) are saved to system.	Certain registers saved to system.	Entire context saved to task stack	--Not applicable--
Context saved when blocked	--Not applicable--	--Not applicable--	Saves the saved-by-callee registers (see optimizing compiler user's guide for your platform).	--Not applicable--
Share data with thread via	Streams, lists, pipes, global variables	Streams, lists, pipes, global variables	Streams, lists, pipes, gates, mailboxes, message queues, global variables	Streams, lists, pipes, global variables
Synchronize with thread via	--Not applicable--	Swi trigger	Semaphores, events, mailboxes	-Not applicable--
Function hooks	Yes: register, create, begin, end, delete	Yes:register, create, ready, begin, end, delete	Yes: register, create, ready, switch, exit, delete	No
Static creation	Yes	Yes	Yes	Yes
Dynamic creation	Yes	Yes	Yes	No
Dynamically change priority	See Note 1	Yes	Yes	No
Implicit logging	Interrupt event	Post, begin, end	Switch, yield, ready, exit	None
Implicit statistics	None	None	None	None

Notes: 1) Some devices allow hardware interrupt priorities to be modified.

2.2.4 Thread Priorities

Within SYS/BIOS, hardware interrupts have the highest priority. The priorities among the set of Hwi objects are not maintained implicitly by SYS/BIOS. The Hwi priority only applies to the order in which multiple interrupts that are ready on a given CPU cycle are serviced by the CPU. Hardware interrupts are preempted by another interrupt unless interrupts are globally disabled or when specific interrupts are individually disabled.

Figure 2-1. Thread Priorities

Swis have lower priority than Hwis. There are up to 32 priority levels available for Swis (16 by default). The maximum number of priority levels is 16 for MSP430 and C28x. Swis can be preempted by a higher-priority Swi or any Hwi. Swis cannot block.

Tasks have lower priority than Swis. There are up to 32 task priority levels (16 by default). The maximum number of priority levels is 16 for MSP430 and C28x. Tasks can be preempted by any higher-priority thread. Tasks can block while waiting for resource availability and lower-priority threads.

The background Idle Loop is the thread with the lowest priority of all. It runs in a loop when the CPU is not busy running another thread. When tasks are enabled, the Idle Loop is implemented as the only task running at priority 0. When tasks are disabled, the Idle Loop is fallen into after the application's "main()" function is called.

2.2.5 Yielding and Preemption

The SYS/BIOS thread schedulers run the highest-priority thread that is ready to run except in the following cases:

- ❑ The thread that is running disables some or all hardware interrupts temporarily with `Hwi_disable()` or `Hwi_disableInterrupt()`, preventing hardware ISRs from running.
- ❑ The thread that is running disables Swis temporarily with `Swi_disable()`. This prevents any higher-priority Swi from preempting the current thread. It does not prevent Hwis from preempting the current thread.
- ❑ The thread that is running disables task scheduling temporarily with `Task_disable()`. This prevents any higher-priority task from preempting the current task. It does not prevent Hwis and Swis from preempting the current task.
- ❑ If a lower priority task shares a gating resource with a higher task and changes its state to pending, the higher priority task may effectively have its priority set to that of the lower priority task. This is called Priority Inversion and is described in Section 3.3.3.

Both Hwis and Swis can interact with the SYS/BIOS task scheduler. When a task is blocked, it is often because the task is pending on a semaphore which is unavailable. Semaphores can be posted from Hwis and Swis as well as from other tasks. If a Hwi or Swi posts a semaphore to unblock a pending task, the processor switches to that task if that task has a higher priority than the currently running task (after the Hwi or Swi completes).

When running either a Hwi or Swi, SYS/BIOS uses a dedicated system interrupt stack, called the *system stack* (sometimes called the ISR stack). Each task uses its own private stack. Therefore, if there are no Tasks in the system, all threads share the same system stack. For performance reasons, sometimes it is advantageous to place the system stack in precious fast memory. See Section 2.4.3 for information about system stack size and Section 2.5.3 for information about task stack size.

Table 2-2 shows what happens when one type of thread is running (top row) and another thread becomes ready to run (left column). The action shown is that of the newly posted (ready to run) thread.

Table 2-2. Thread Preemption

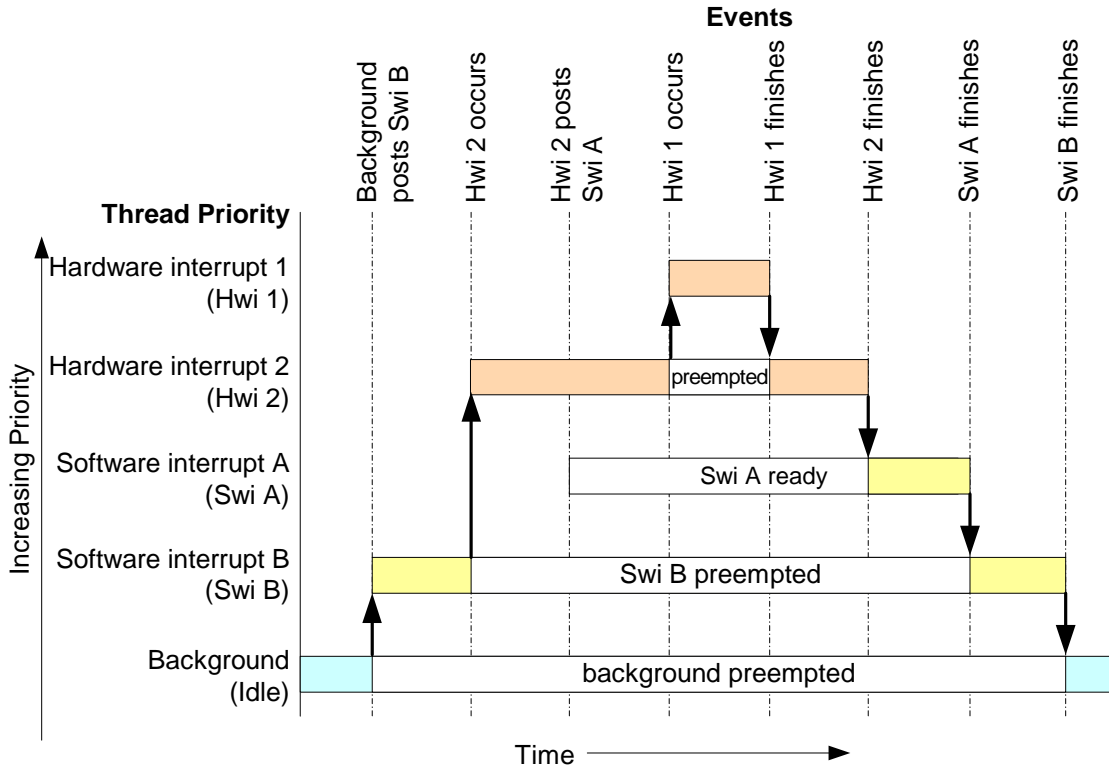

Newly Posted Thread	Running Thread			
	Hwi	Swi	Task	Idle
Enabled Hwi	Preempts if enabled*	Preempts	Preempts	Preempts
Disabled Hwi	Waits for reenable	Waits for reenable	Waits for reenable	Waits for reenable
Enabled, higher-priority Swi	Waits	Preempts	Preempts	Preempts
Lower-priority Swi	Waits	Waits	Preempts	Preempts
Enabled, higher-priority Task	Waits	Waits	Preempts	Preempts
Low-priority Task	Waits	Waits	Waits	Preempts

* On some targets, hardware interrupts can be individually enabled and disabled. This is not true on all targets. Also, some targets have controllers that support hardware interrupt prioritization, in which case a Hwi can only be preempted by a higher-priority Hwi.

Note that Table 2-2 shows the results if the type of thread that is posted is enabled. If that thread type is disabled (for example, by Task_disable), a thread cannot run in any case until its thread type is reenabled.

Figure 2-2 shows the execution graph for a scenario in which Swis and Hwis are enabled (the default), and a Hwi posts a Swi whose priority is higher than that of the Swi running when the interrupt occurs. Also, a second Hwi occurs while the first ISR is running and preempts the first ISR.

Figure 2-2. Preemption Scenario

In Figure 2-2, the low-priority Swi is asynchronously preempted by the Hwis. The first Hwi posts a higher-priority Swi, which is executed after both Hwis finish executing.

Here is sample pseudo-code for the example depicted in Figure 2-2:

```
backgroundThread()
{
    Swi_post(Swi_B) /* priority = 5 */
}

Hwi_1 ()
{
    . . .
}

Hwi_2 ()
{
    Swi_post(Swi_A) /* priority = 7 */
}
```

2.2.6 Hooks

Hwi, Swi, and Task threads optionally provide points in a thread's life cycle to insert user code for instrumentation, monitoring, or statistics gathering purposes. Each of these code points is called a "hook" and the user function provided for the hook is called a "hook function".

The following hook functions can be set for the various thread types:

Table 2–3 Hook Functions by Thread Type

Thread Type	Hook Functions
Hwi	Register, Create, Begin, End, and Delete. See Section 2.3.2.
Swi	Register, Create, Ready, Begin, End, and Delete. See Section 2.4.8.
Task	Register, Create, Ready, Switch, Exit, and Delete. See Section 2.5.5.

Hooks are declared as a set of hook functions called "hook sets". You do not need to define all hook functions within a set, only those that are required by the application.

Hook functions can only be declared statically (in an XDCtools configuration script) so that they may be efficiently invoked when provided and result in *no runtime overhead* when a hook function is not provided.

Except for the Register hook, all hook functions are invoked with a handle to the object associated with that thread as its argument (that is, a Hwi object, a Swi object, or a Task object). Other arguments are provided for some thread-type-specific hook functions.

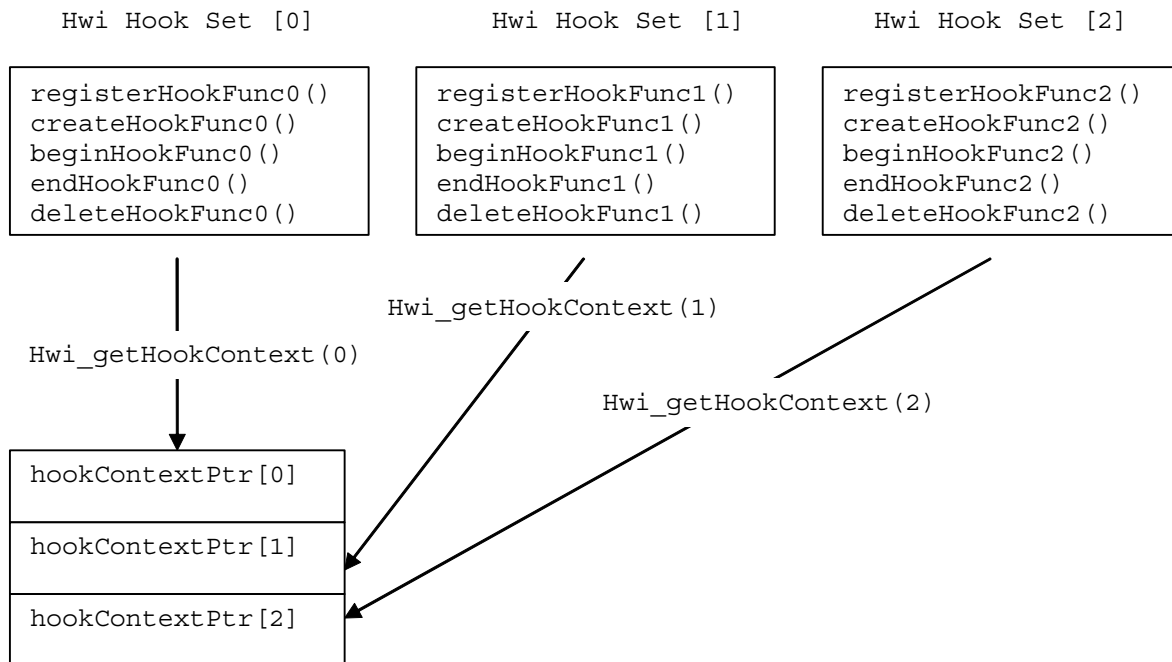

You can define as many hook sets as necessary for your application. When more than one hook set is defined, the individual hook functions within each set are invoked in hook ID order for a particular hook type. For example, during `Task_create()` the order that the Create hook within each Task hook set is invoked is the order in which the Task hook sets were originally defined.

The argument to a thread's Register hook (which is invoked only once) is an index (the "hook ID") indicating the hook set's relative order in the hook function calling sequence.

Each set of hook functions has a unique associated "hook context pointer". This general-purpose pointer can be used by itself to hold hook set specific information, or it can be initialized to point to a block of memory allocated by the Create hook function within a hook set if more space is required for a particular application.

An individual hook function obtains the value of its associated context pointer through the following thread-type-specific APIs: `Hwi_getHookContext()`, `Swi_getHookContext()`, and `Task_getHookContext()`. Corresponding APIs for initializing the context pointers are also provided: `Hwi_setHookContext()`, `Swi_setHookContext()`, and `Task_setHookContext()`. Each of these APIs take the hook ID as an argument.

The following diagram shows an application with three Hwi hook sets:

The hook context pointers are accessed using `Hwi_getHookContext()` using the index provided to the three Register hook functions.

Just prior to invoking your ISR functions, the Begin Hook functions are invoked in the following order:

- 1) `beginHookFunc0()`;
- 2) `beginHookFunc1()`;
- 3) `beginHookFunc2()`;

Likewise, upon return from your ISR functions the End Hook functions are invoked in the following order:

- 1) `endHookFunc0()`;
- 2) `endHookFunc1()`;
- 3) `endHookFunc2()`;

2.3 Hardware Interrupts

Hardware interrupts (Hwis) handle critical processing that the application must perform in response to external asynchronous events. The SYS/BIOS target/device specific Hwi modules are used to manage hardware interrupts.

In a typical embedded system, hardware interrupts are triggered either by on-device peripherals or by devices external to the processor. In both cases, the interrupt causes the processor to vector to the ISR address.

Any interrupt processing that may invoke SYS/BIOS APIs that affect Swi and Task scheduling must be written in C or C++. The HWI_enter()/HWI_exit() macros provided in earlier versions of SYS/BIOS for calling assembly language ISRs are no longer provided.

Assembly language ISRs that do not interact with SYS/BIOS can be specified with Hwi_plug(). Such ISRs must do their own context preservation. They may use the "interrupt" keyword, C functions, or assembly language functions.

All hardware interrupts run to completion. If a Hwi is posted multiple times before its ISR has a chance to run, the ISR runs only one time. For this reason, you should minimize the amount of code performed by a Hwi function.

If interrupts are globally enabled—that is, by calling Hwi_enable()—an ISR can be preempted by any interrupt that has been enabled.

Hwis must not use the Chip Support Library (CSL) for the target. Instead, see Chapter 6 for a description of Hardware Abstraction Layer APIs.

Associating an ISR function with a particular interrupt is done by creating a Hwi object.

2.3.1 Creating Hwi Objects

The Hwi module maintains a table of pointers to Hwi objects that contain information about each Hwi managed by the dispatcher. To create a Hwi object dynamically, use calls similar to these:

```
Hwi_Handle hwi0;
Hwi_Params hwiParams;
Hwi_Params_init(&hwiParams);

hwiParams.arg = 5;
hwi0 = Hwi_create(id, hwiFunc, &hwiParams, &eb);
```

Here, hwi0 is a handle to the created Hwi object, id is the interrupt number being defined, hwiFunc is the name of the function associated with the Hwi, and hwiParams is a structure that contains Hwi instance parameters (enable/restore masks, the Hwi function argument, etc). Here, hwiParams.arg is set to 5. If NULL is passed instead of a pointer to an actual Hwi_Params struct, a default set of parameters is used. The "eb" is an error block that you can use to handle errors that may occur during Hwi object creation.

The corresponding static configuration Hwi object creation syntax is:

```
var Hwi = xdc.useModule('ti.sysbios.hal.Hwi');
var hwiParams = new Hwi.Params;

hwiParams.arg = 5;
Program.global.hwi0 = Hwi.create(id, '&hwiFunc', hwiParams);
```

Here, the "hwiParams = new Hwi.Params" statement does the equivalent of creating and initializing the hwiParams structure with default values. In the static configuration world, no error block (eb) is required for the "create" function. The "Program.global.hwi0" name becomes a runtime-accessible handle (symbol name = "hwi0") to the statically-created Hwi object.

2.3.2 Hwi Hooks

The Hwi module supports the following set of Hook functions:

- ❑ **Register.** A function called before any statically created Hwis are initialized at runtime. The register hook is called at boot time before main() and before interrupts are enabled.
- ❑ **Create.** A function called when a Hwi is created. This includes Hwis that are created statically and those created dynamically using Hwi_create().
- ❑ **Begin.** A function called just prior to running a Hwi ISR function.
- ❑ **End.** A function called just after a Hwi ISR function finishes.
- ❑ **Delete.** A function called when a Hwi is deleted at runtime with Hwi_delete().

The following HookSet structure type definition encapsulates the hook functions supported by the Hwi module:

```
typedef struct Hwi_HookSet {
    Void (*registerFxn) (Int);           /* Register Hook */
    Void (*createFxn) (Handle, Error.Block *); /* Create Hook */
    Void (*beginFxn) (Handle);         /* Begin Hook */
    Void (*endFxn) (Handle);           /* End Hook */
    Void (*deleteFxn) (Handle);        /* Delete Hook */
};
```

Hwi Hook functions can only be configured statically.

2.3.2.1 Register Function

The register function is provided to allow a hook set to store its corresponding hook ID. This ID can be passed to `Hwi_setHookContext()` and `Hwi_getHookContext()` to set or get hook-specific context. The Register function must be specified if the hook implementation needs to use `Hwi_setHookContext()` or `Hwi_getHookContext()`.

The `registerFxn` hook function is called during system initialization before interrupts have been enabled.

The Register function has the following signature:

```
Void registerFxn(Int id);
```

2.3.2.2 Create and Delete Functions

The Create and Delete functions are called whenever a Hwi is created or deleted. The Create function is passed an `Error_Block` that is to be passed to `Memory_alloc()` for applications that require additional context storage space.

The `createFxn` and `deleteFxn` functions are called with interrupts enabled (unless called at boot time or from `main()`).

These functions have the following signatures:

```
Void createFxn(Hwi_Handle hwi, Error_Block *eb);
Void deleteFxn(Hwi_Handle hwi);
```

2.3.2.3 Begin and End Functions

The Begin and End hook functions are called with interrupts globally disabled. As a result, any hook processing function contributes to overall system interrupt response latency. In order to minimize this impact, carefully consider the processing time spent in a Hwi `beginFxn` or `endFxn` hook function.

The beginFxn is invoked just prior to calling the ISR function. The endFxn is invoked immediately after the return from the ISR function.

These functions have the following signatures:

```
Void beginFxn(Hwi_Handle hwi);  
Void endFxn(Hwi_Handle hwi);
```

When more than one Hook Set is defined, the individual hook functions of a common type are invoked in hook ID order.

2.3.2.4 Hwi Hooks Example

The following example application uses two Hwi hook sets. The Hwi associated with a statically-created Timer is used to exercise the Hwi hook functions. This example demonstrates how to read and write the Hook Context Pointer associated with each hook set.

The XDCtools configuration script and program output are shown after the C code listing.

This is the C code for the example:

```
/* ===== HwiHookExample.c =====  
 * This example demonstrates basic Hwi hook usage. */  
  
#include <xdc/std.h>  
#include <xdc/runtime/Error.h>  
#include <xdc/runtime/System.h>  
#include <xdc/runtime/Timestamp.h>  
  
#include <ti/sysbios/BIOS.h>  
#include <ti/sysbios/knl/Task.h>  
#include <ti/sysbios/hal/Timer.h>  
#include <ti/sysbios/hal/Hwi.h>  
  
extern Timer_Handle myTimer;  
volatile Bool myEnd2Flag = FALSE;  
Int myHookSetId1, myHookSetId2;  
  
/* HookSet 1 functions */
```

```
/* ===== myRegister1 =====
 * invoked during Hwi module startup before main()
 * for each HookSet */
Void myRegister1(Int hookSetId)
{
    System_printf("myRegister1: assigned hookSet Id = %d\n",
                  hookSetId);
    myHookSetId1 = hookSetId;
}

/* ===== myCreate1 =====
 * invoked during Hwi module startup before main()
 * for statically created Hwis */
Void myCreate1(Hwi_Handle hwi, Error_Block *eb)
{
    Ptr pEnv;

    pEnv = Hwi_getHookContext(hwi, myHookSetId1);
    /* pEnv should be 0 at this point. If not, there's a bug. */
    System_printf("myCreate1: pEnv = 0x%x, time = %d\n", pEnv,
                  Timestamp_get32());
    Hwi_setHookContext(hwi, myHookSetId1, (Ptr)0xdead1);
}

/* ===== myBegin1 =====
 * invoked before Timer Hwi func */
Void myBegin1(Hwi_Handle hwi)
{
    Ptr pEnv;

    pEnv = Hwi_getHookContext(hwi, myHookSetId1);
    System_printf("myBegin1: pEnv = 0x%x, time = %d\n", pEnv,
                  Timestamp_get32());
    Hwi_setHookContext(hwi, myHookSetId1, (Ptr)0xbeef1);
}
```

```
/* ===== myEnd1 =====
 * invoked after Timer Hwi func */
Void myEnd1(Hwi_Handle hwi)
{
    Ptr pEnv;

    pEnv = Hwi_getHookContext(hwi, myHookSetId1);
    System_printf("myEnd1: pEnv = 0x%x, time = %d\n", pEnv,
                  Timestamp_get32());
    Hwi_setHookContext(hwi, myHookSetId1, (Ptr)0xc0de1);
}

/* HookSet 2 functions */
/* ===== myRegister2 =====
 * invoked during Hwi module startup before main
 * for each HookSet */
Void myRegister2(Int hookSetId)
{
    System_printf("myRegister2: assigned hookSet Id = %d\n",
                  hookSetId);
    myHookSetId2 = hookSetId;
}

/* ===== myCreate2 =====
 * invoked during Hwi module startup before main
 * for statically created Hwis */
Void myCreate2(Hwi_Handle hwi, Error_Block *eb)
{
    Ptr pEnv;

    pEnv = Hwi_getHookContext(hwi, myHookSetId2);
    /* pEnv should be 0 at this point. If not, there's a bug. */
    System_printf("myCreate2: pEnv = 0x%x, time = %d\n", pEnv,
                  Timestamp_get32());
    Hwi_setHookContext(hwi, myHookSetId2, (Ptr)0xdead2);
}

/* ===== myBegin2 =====
 * invoked before Timer Hwi func */
Void myBegin2(Hwi_Handle hwi)
{
    Ptr pEnv;

    pEnv = Hwi_getHookContext(hwi, myHookSetId2);
    System_printf("myBegin2: pEnv = 0x%x, time = %d\n", pEnv,
                  Timestamp_get32());
    Hwi_setHookContext(hwi, myHookSetId2, (Ptr)0xbeef2);
}
```

```
/* ===== myEnd2 =====
 * invoked after Timer Hwi func */
Void myEnd2(Hwi_Handle hwi)
{
    Ptr pEnv;

    pEnv = Hwi_getHookContext(hwi, myHookSetId2);
    System_printf("myEnd2: pEnv = 0x%x, time = %d\n", pEnv,
                  Timestamp_get32());
    Hwi_setHookContext(hwi, myHookSetId2, (Ptr)0xc0de2);
    myEnd2Flag = TRUE;
}

/* ===== myTimerFunc =====
 * Timer interrupt handler */
Void myTimerFunc(UArg arg)
{
    System_printf("Entering myTimerHwi\n");
}

/* ===== myTaskFunc ===== */
Void myTaskFunc(UArg arg0, UArg arg1)
{
    System_printf("Entering myTask.\n");

    Timer_start(myTimer);
    /* wait for timer interrupt and myEnd2 to complete */
    while (!myEnd2Flag) {
        ;
    }
    System_printf("myTask exiting ...\n");
}

/* ===== myIdleFunc ===== */
Void myIdleFunc()
{
    System_printf("Entering myIdleFunc().\n");
    System_exit(0);
}
```

```
/* ===== main ===== */
Int main(Int argc, Char* argv[])
{
    System_printf("Starting HwiHookExample...\n");
    BIOS_start();
    return (0);
}
```

This is the XDCtools configuration script for the example:

```
/* pull in Timestamp to print time in hook functions */
xdc.useModule('xdc.runtime.Timestamp');

/* Disable Clock so that ours is the only Timer allocated */
var BIOS = xdc.useModule('ti.sysbios.BIOS');
BIOS.clockEnabled = false;

var Idle = xdc.useModule('ti.sysbios.knl.Idle');
Idle.addFunc('&myIdleFunc');

/* Create myTask with default task params */
var Task = xdc.useModule('ti.sysbios.knl.Task');
var taskParams = new Task.Params();
Program.global.myTask = Task.create('&myTaskFunc', taskParams);

/* Create myTimer as source of Hwi */
var Timer = xdc.useModule('ti.sysbios.hal.Timer');
var timerParams = new Timer.Params();
timerParams.startMode = Timer.StartMode_USER;
timerParams.runMode = Timer.RunMode_ONESHOT;
timerParams.period = 1000; // 1ms
Program.global.myTimer = Timer.create(Timer.ANY,
    "&myTimerFunc", timerParams);
```

```
/* Define and add two Hwi HookSets
 * Notice, no deleteFxn is provided.
 */
var Hwi = xdc.useModule('ti.sysbios.hal.Hwi');

/* Hook Set 1 */
Hwi.addHookSet({
    registerFxn: '&myRegister1',
    createFxn: '&myCreate1',
    beginFxn: '&myBegin1',
    endFxn: '&myEnd1',
});

/* Hook Set 2 */
Hwi.addHookSet({
    registerFxn: '&myRegister2',
    createFxn: '&myCreate2',
    beginFxn: '&myBegin2',
    endFxn: '&myEnd2',
});
```

The program output is as follows:

```
myRegister1: assigned hookSet Id = 0
myRegister2: assigned hookSet Id = 1
myCreate1: pEnv = 0x0, time = 0
myCreate2: pEnv = 0x0, time = 0
Starting HwiHookExample...
Entering myTask.
myBegin1: pEnv = 0xdead1, time = 75415
myBegin2: pEnv = 0xdead2, time = 75834
Entering myTimerHwi
myEnd1: pEnv = 0xbeef1, time = 76427
myEnd2: pEnv = 0xbeef2, time = 76830
myTask exiting ...
Entering myIdleFunc().
```

2.4 Software Interrupts

Software interrupts are patterned after hardware ISRs. The Swi module in SYS/BIOS provides a software interrupt capability. Software interrupts are triggered programmatically, through a call to a SYS/BIOS API such as Swi_post(). Software interrupts have priorities that are higher than tasks but lower than hardware interrupts.

Note: The Swi module should not be confused with the SWI instruction that exists on many processors. The SYS/BIOS Swi module is independent from any target/device-specific software interrupt features.

Swi threads are suitable for handling application tasks that occur at slower rates or are subject to less severe real-time deadlines than those of Hwis.

The SYS/BIOS APIs that can trigger or post a Swi are:

- Swi_andn()
- Swi_dec()
- Swi_inc()
- Swi_or()
- Swi_post()

The Swi Manager controls the execution of all Swi functions. When the application calls one of the APIs above, the Swi Manager schedules the function corresponding to the specified Swi for execution. To handle Swi functions, the Swi Manager uses Swi objects.

If a Swi is posted, it runs only after all pending Hwis have run. A Swi function in progress can be preempted at any time by a Hwi; the Hwi completes before the Swi function resumes. On the other hand, Swi functions always preempt tasks. All pending Swis run before even the highest priority task is allowed to run. In effect, a Swi function is like a task with a priority higher than all ordinary tasks.

Note:

Two things to remember about Swi functions are:

A Swi function runs to completion unless it is interrupted by a Hwi or preempted by a higher-priority Swi.

Any hardware ISR that triggers or posts a Swi must have been invoked by the Hwi dispatcher. That is, the Swi must be triggered by a function called from a Hwi object.

2.4.1 Creating Swi Objects

As with many other SYS/BIOS objects, you can create Swi objects either dynamically—with a call to `Swi_create()`—or statically in the configuration. Swis you create dynamically can also be deleted during program execution.

To add a new Swi to the configuration, create a new Swi object in the configuration script. Set the function property for each Swi to run a function when the object is triggered by the application. You can also configure up to two arguments to be passed to each Swi function.

As with all modules with instances, you can determine from which memory segment Swi objects are allocated. Swi objects are accessed by the Swi Manager when Swis are posted and scheduled for execution.

For complete reference information on the Swi API, configuration, and objects, see the Swi module in the "ti.sysbios.knl" package documentation in the online documentation. (For information on running online help, see Section 1.6.1, *Using the API Reference Help System*, page 1-10.)

To create a Swi object dynamically, use a call with this syntax:

```
Swi_Handle swi0;
Swi_Params swiParams;
Swi_Params_init(&swiParams);

swi0 = Swi_create(swiFunc, &swiParams, &eb);
```

Here, `swi0` is a handle to the created Swi object, `swiFunc` is the name of the function associated with the Swi, and `swiParams` is a structure of type `Swi_Params` that contains the Swi instance parameters (priority, `arg0`, `arg1`, etc). If `NULL` is passed instead of a pointer to an actual `Swi_Params` struct, a default set of parameters is used. "eb" is an error block you can use to handle errors that may occur during Swi object creation.

Note:

`Swi_create()` cannot be called from the context of a Hwi or another Swi thread. Applications that dynamically create Swi threads must do so from either the context of the `main()` function or a Task thread.

To create a Swi object in an XDCtools configuration file, use statements like these:

```
var Swi = xdc.useModule('ti.sysbios.knl.Swi');
var swiParams = new Swi.Params();
program.global.swi0 = Swi.create(swiParams);
```

2.4.2 Setting Software Interrupt Priorities

There are different priority levels among Swis. You can create as many Swis as your memory constraints allow for each priority level. You can choose a higher priority for a Swi that handles a thread with a shorter real-time deadline, and a lower priority for a Swi that handles a thread with a less critical execution deadline.

The number of Swi priorities supported within an application is configurable up to a maximum 32. The maximum number of priority levels is 16 for MSP430 and C28x. The default number of priority levels is 16. The lowest priority level is 0. Thus, by default, the highest priority level is 15.

You cannot sort Swis within a single priority level. They are serviced in the order in which they were posted.

2.4.3 Software Interrupt Priorities and Application Stack Size

When a Swi is posted, its associated Swi function is invoked using the system stack. While you can have up to 32 Swi priority levels on some targets, keep in mind that in the worst case, each Swi priority level can result in a nesting of the Swi scheduling function (that is, the lowest priority Swi is preempted by the next highest priority Swi, which, in turn, is preempted by the next highest, ...). This results in an increasing stack size requirement for each Swi priority level actually used. Thus, giving Swis the same priority level is more efficient in terms of stack size than giving each Swi a separate priority.

The default system stack size is 4096 bytes. You can set the system stack size by adding the following line to your config script:

```
Program.stack = yourStackSize;
```

<p>Note: The Clock module creates and uses a Swi with the maximum Swi priority (that is, if there are 16 Swi priorities, the Clock Swi has priority 15).</p>

The following table shows the amount of system stack required to absorb the worst-case Swi interrupt nesting. This first number is the amount of system stack space required for the first priority level on a target. The second number shows the amount of stack space required for each subsequent priority level used in the application.

Table 2–4 System Stack Use for Swi Nesting by Target Family

Target Family	Stack Consumed by First Priority Level	Stack Consumed by Subsequent Priority Levels	Units
M3	104	88	8-bit bytes
MSP430	78	32	8-bit bytes
MSP430X	90	60	8-bit bytes
MSP430X_small	78	32	8-bit bytes
C674	108	120	8-bit bytes
C64P	108	120	8-bit bytes
C64T	108	120	8-bit bytes
C28_float	83	40	16-bit words
C28_large	81	34	16-bit words
Arm9	104	80	8-bit bytes

See Section 2.5.3 for information about task stack size.

2.4.4 Execution of Software Interrupts

Swis can be scheduled for execution with a call to `Swi_andn()`, `Swi_dec()`, `Swi_inc()`, `Swi_or()`, and `Swi_post()`. These calls can be used virtually anywhere in the program—Hwi functions, Clock functions, Idle functions, or other Swi functions.

When a Swi is posted, the Swi Manager adds it to a list of posted Swis that are pending execution. The Swi Manager checks whether Swis are currently enabled. If they are not, as is the case inside a Hwi function, the Swi Manager returns control to the current thread.

If Swis are enabled, the Swi Manager checks the priority of the posted Swi object against the priority of the thread that is currently running. If the thread currently running is the background Idle Loop or a lower priority Swi, the Swi Manager removes the Swi from the list of posted Swi objects and switches the CPU control from the current thread to start execution of the posted Swi function.

If the thread currently running is a Swi of the same or higher priority, the Swi Manager returns control to the current thread, and the posted Swi function runs after all other Swis of higher priority or the same priority that were previously posted finish execution.

When multiple Swis of the same priority level have been posted, their respective Swi functions are executed in the order the Swis were posted.

There are two important things to remember about Swi:

- ❑ When a Swi starts executing, it must run to completion without blocking.
- ❑ When called from within a hardware ISR, the code calling any Swi function that can trigger or post a Swi must be invoked by the Hwi dispatcher. That is, the Swi must be triggered by a function called from a Hwi object.

Swi functions can be preempted by threads of higher priority (such as a Hwi or a Swi of higher priority). However, Swi functions cannot block. You cannot suspend a Swi while it waits for something—like a device—to be ready.

If a Swi is posted multiple times before the Swi Manager has removed it from the posted Swi list, its Swi function executes only once, much like a Hwi is executed only once if the Hwi is triggered multiple times before the CPU clears the corresponding interrupt flag bit in the interrupt flag register. (See Section 2.4.5 for more information on how to handle Swis that are posted multiple times before they are scheduled for execution.)

Applications should not make any assumptions about the order in which Swi functions of equal priority are called. However, a Swi function can safely post itself (or be posted by another interrupt). If more than one is pending, all Swi functions are called before any tasks run.

2.4.5 Using a Swi Object's Trigger Variable

Each Swi object has an associated 32-bit trigger variable for C6x targets and a 16-bit trigger variable for C5x, C28x, and MSP430 targets. This is used either to determine whether to post the Swi or to provide values that can be evaluated within the Swi function.

`Swi_post()`, `Swi_or()`, and `Swi_inc()` post a Swi object unconditionally:

- ❑ `Swi_post()` does not modify the value of the Swi object trigger when it is used to post a Swi.
- ❑ `Swi_or()` sets the bits in the trigger determined by a mask that is passed as a parameter, and then posts the Swi.
- ❑ `Swi_inc()` increases the Swi's trigger value by one before posting the Swi object.

`Swi_andn()` and `Swi_dec()` post a Swi object only if the value of its trigger becomes 0:

- ❑ `Swi_andn()` clears the bits in the trigger determined by a mask passed as a parameter.
- ❑ `Swi_dec()` decreases the value of the trigger by one.

Table 2-5 summarizes the differences between these functions.

Table 2-5. Swi Object Function Differences

Action	Treats Trigger as Bitmask	Treats Trigger as Counter	Does not Modify Trigger
Always post	<code>Swi_or()</code>	<code>Swi_inc()</code>	<code>Swi_post()</code>
Post if it becomes zero	<code>Swi_andn()</code>	<code>Swi_dec()</code>	—

The Swi trigger allows you to have tighter control over the conditions that should cause a Swi function to be posted, or the number of times the Swi function should be executed once the Swi is posted and scheduled for execution.

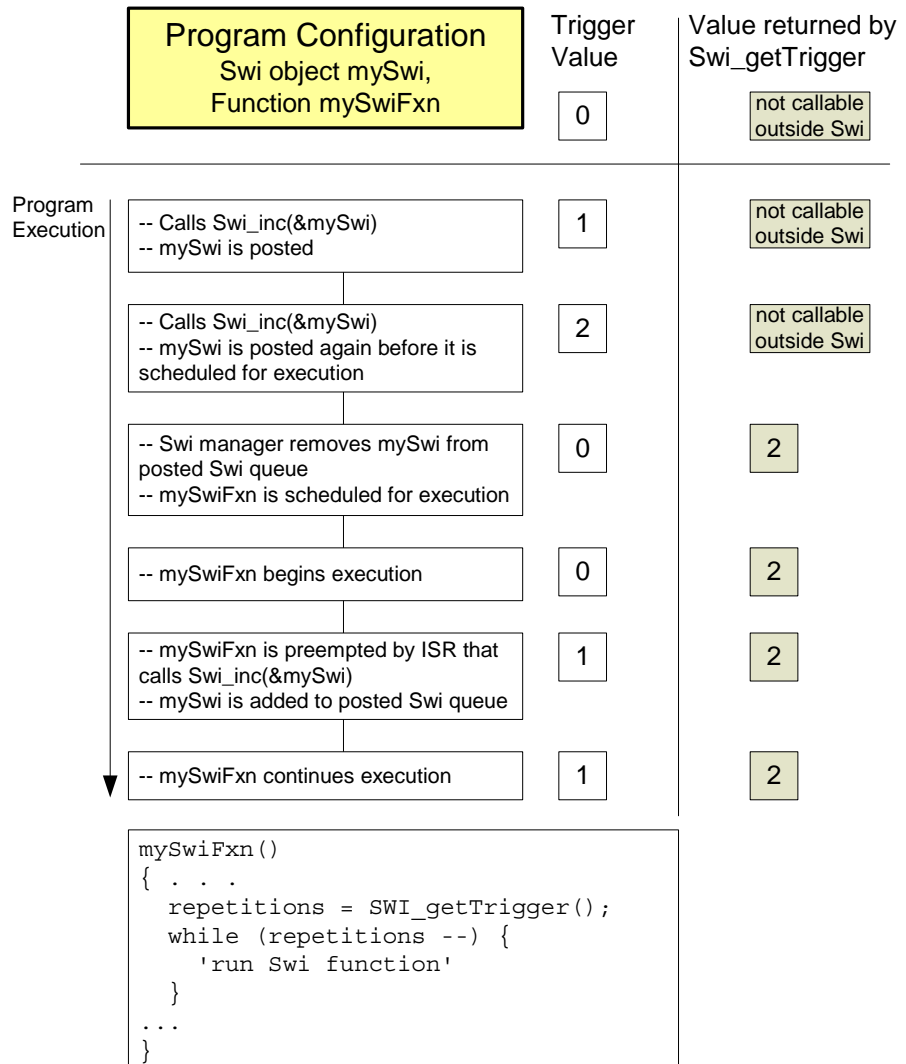

To access the value of its trigger, a Swi function can call `Swi_getTrigger()`. `Swi_getTrigger()` can be called only from the Swi object's function. The value returned by `Swi_getTrigger()` is the value of the trigger before the Swi object was removed from the posted Swi queue and the Swi function was scheduled for execution.

When the Swi Manager removes a pending Swi object from the posted object's queue, its trigger is reset to its initial value. The initial value of the trigger should be set in the application's configuration script. If while the Swi function is executing, the Swi is posted again, its trigger is updated accordingly. However, this does not affect the value returned by `Swi_getTrigger()` while the Swi function executes. That is, the trigger value that `Swi_getTrigger()` returns is the latched trigger value when the Swi was removed from the list of pending Swis. The Swi's trigger however, is immediately reset after the Swi is removed from the list of pending Swis and scheduled for execution. This gives the application the ability to keep updating the value of the Swi trigger if a new posting occurs, even if the Swi function has not finished its execution.

For example, if a Swi object is posted multiple times before it is removed from the queue of posted Swis, the Swi Manager schedules its function to execute only once. However, if a Swi function must always run multiple times when the Swi object is posted multiple times, `Swi_inc()` should be used to post the Swi as shown in Figure 2-3.

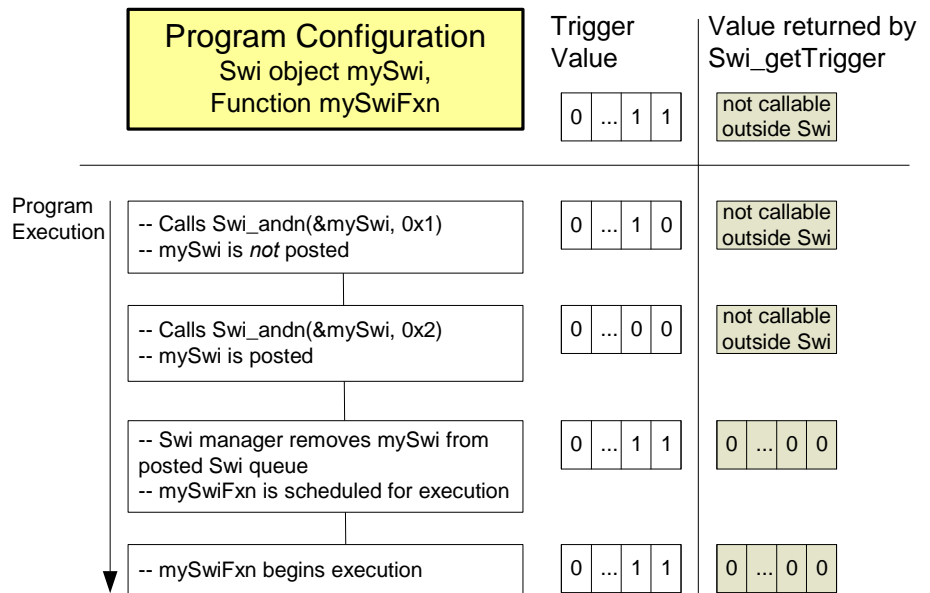

When a Swi has been posted using `Swi_inc()`, once the Swi Manager calls the corresponding Swi function for execution, the Swi function can access the Swi object trigger to know how many times it was posted before it was scheduled to run, and proceed to execute the same function as many times as the value of the trigger.

Figure 2-3. Using `Swi_inc()` to Post a Swi

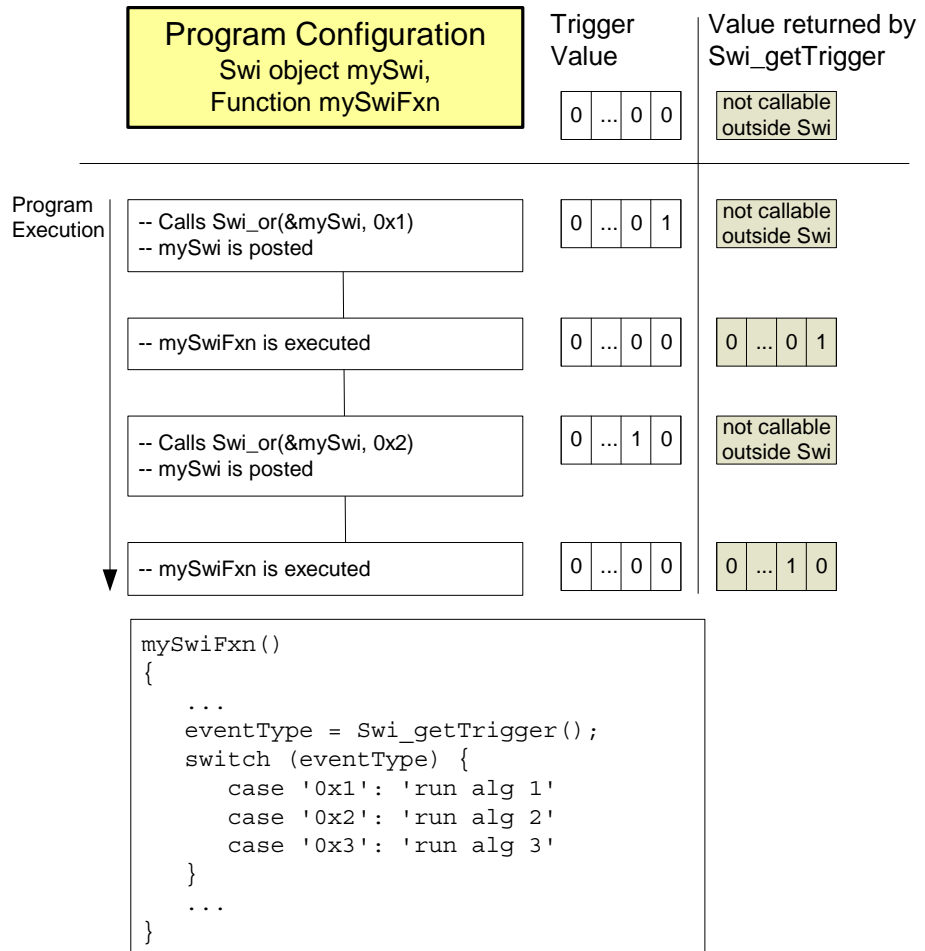

If more than one event must always happen for a given Swi to be triggered, `Swi_andn()` should be used to post the corresponding Swi object as shown in Figure 2-4. For example, if a Swi must wait for input data from two different devices before it can proceed, its trigger should have two set bits when the Swi object is configured. When both functions that provide input data have completed their tasks, they should both call `Swi_andn()` with complementary bitmasks that clear each of the bits set in the Swi trigger default value. Hence, the Swi is posted only when data from both processes is ready.

Figure 2-4. Using `Swi_andn()` to Post a Swi

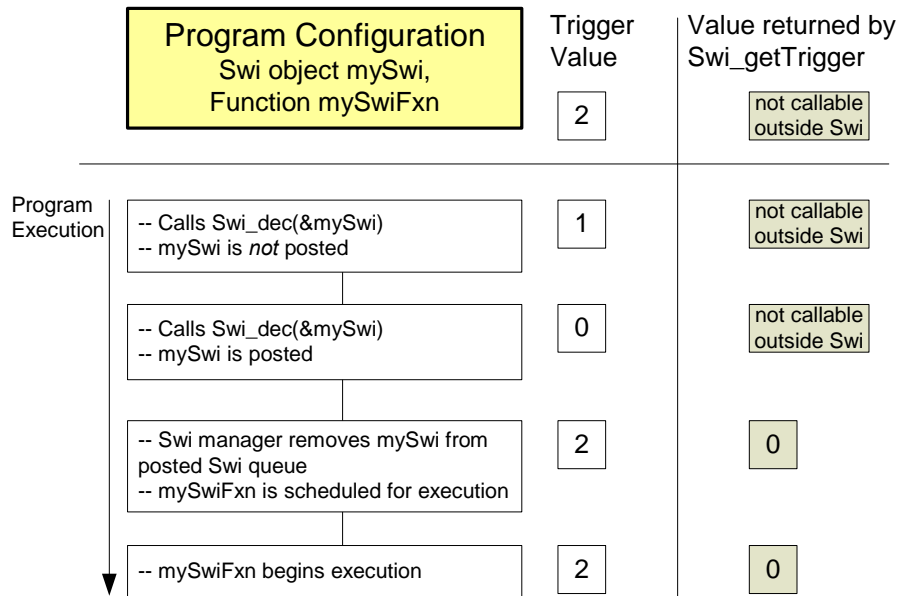

In some situations the Swi function can call different functions depending on the event that posted it. In that case the program can use Swi_or() to post the Swi object unconditionally when an event happens. This is shown in Figure 2-5. The value of the bitmask used by Swi_or() encodes the event type that triggered the post operation, and can be used by the Swi function as a flag that identifies the event and serves to choose the function to execute.

Figure 2-5. Using Swi_or() to Post a Swi.

If the program execution requires that multiple occurrences of the same event must take place before a Swi is posted, `Swi_dec()` should be used to post the Swi as shown in Figure 2-6. By configuring the Swi trigger to be equal to the number of occurrences of the event before the Swi should be posted and calling `Swi_dec()` every time the event occurs, the Swi is posted only after its trigger reaches 0; that is, after the event has occurred a number of times equal to the trigger value.

Figure 2-6. Using `Swi_dec()` to Post a Swi

2.4.6 Benefits and Tradeoffs

There are several benefits to using Swis instead of Hwis:

- ❑ By modifying shared data structures in a Swi function instead of a Hwi, you can get mutual exclusion by disabling Swis while a Task accesses the shared data structure (see page 2–34). This allows the system to respond to events in real-time using Hwis. In contrast, if a Hwi function modified a shared data structure directly, Tasks would need to disable Hwis to access data structures in a mutually exclusive way. Obviously, disabling Hwis may degrade the performance of a real-time system.
- ❑ It often makes sense to break long ISRs into two pieces. The Hwi takes care of the extremely time-critical operation and defers less critical processing to a Swi function by posting the Swi within the Hwi function.

Remember that a Swi function must complete before any blocked Task is allowed to run.

2.4.7 Synchronizing Swi Functions

Within an Idle, Task, or Swi function, you can temporarily prevent preemption by a higher-priority Swi by calling `Swi_disable()`, which disables all Swi preemption. To reenable Swi preemption, call `Swi_restore()`.

Swis are enabled or disabled as a group. An individual Swi cannot be enabled or disabled on its own.

When SYS/BIOS finishes initialization and before the first task is called, Swis have been enabled. If an application wishes to disable Swis, it calls `Swi_disable()` as follows:

```
key = Swi_disable();
```

The corresponding enable function is `Swi_restore()`.

```
Swi_restore(key);
```

where `key` is a value used by the Swi module to determine if `Swi_disable()` has been called more than once. This allows nesting of `Swi_disable()` / `Swi_restore()` calls, since only the outermost `Swi_restore()` call actually enables Swis. In other words, a task can disable and enable Swis without having to determine if `Swi_disable()` has already been called elsewhere.

When Swis are disabled, a posted Swi function does not run at that time. The interrupt is “latched” in software and runs when Swis are enabled and it is the highest-priority thread that is ready to run.

To delete a dynamically created Swi, use `Swi_delete()`. The memory associated with Swi is freed. `Swi_delete()` can only be called from the task level.

2.4.8 Swi Hooks

The Swi module supports the following set of Hook functions:

- Register.** A function called before any statically created Swis are initialized at runtime. The register hook is called at boot time before `main()` and before interrupts are enabled.
- Create.** A function called when a Swi is created. This includes Swis that are created statically and those created dynamically using `Swi_create()`.
- Ready.** A function called when any Swi becomes ready to run.
- Begin.** A function called just prior to running a Swi function.
- End.** A function called just after returning from a Swi function.

- ❑ **Delete.** A function called when a Swi is deleted at runtime with `Swi_delete()`.

The following `Swi_HookSet` structure type definition encapsulates the hook functions supported by the Swi module:

```
typedef struct Swi_HookSet {
    Void (*registerFxn) (Int);           /* Register Hook */
    Void (*createFxn) (Handle, Error_Block *); /* Create Hook */
    Void (*readyFxn) (Handle);         /* Ready Hook */
    Void (*beginFxn) (Handle);         /* Begin Hook */
    Void (*endFxn) (Handle);           /* End Hook */
    Void (*deleteFxn) (Handle);        /* Delete Hook */
};
```

Swi Hook functions can only be configured statically.

When more than one Hook Set is defined, the individual hook functions of a common type are invoked in hook ID order.

2.4.8.1 Register Function

The Register function is provided to allow a hook set to store its corresponding hook ID. This ID can be passed to `Swi_setHookContext()` and `Swi_getHookContext()` to set or get hook-specific context. The Register function must be specified if the hook implementation needs to use `Swi_setHookContext()` or `Swi_getHookContext()`.

The `registerFxn` function is called during system initialization before interrupts have been enabled.

The Register functions has the following signature:

```
Void registerFxn(Int id);
```

2.4.8.2 Create and Delete Functions

The Create and Delete functions are called whenever a Swi is created or deleted. The Create function is passed an `Error_Block` that is to be passed to `Memory_alloc()` for applications that require additional context storage space.

The `createFxn` and `deleteFxn` functions are called with interrupts enabled (unless called at boot time or from `main()`).

These functions have the following signatures.

```
Void createFxn(Swi_Handle swi, Error_Block *eb);
Void deleteFxn(Swi_Handle swi);
```

2.4.8.3 Ready, Begin and End Functions

The Ready, Begin and End hook functions are called with interrupts enabled. The readyFxn function is called when a Swi is posted and made ready to run. The beginFxn function is called right before the function associated with the given Swi is run. The endFxn function is called right after returning from the Swi function.

Both readyFxn and beginFxn hooks are provided because a Swi may be posted and ready but still pending while a higher-priority thread completes.

These functions have the following signatures:

```
Void readyFxn(Swi_Handle swi);
Void beginFxn(Swi_Handle swi);
Void endFxn(Swi_Handle swi);
```

2.4.8.4 Swi Hooks Example

The following example application uses two Swi hook sets. This example demonstrates how to read and write the Hook Context Pointer associated with each hook set.

The XDCtools configuration script and program output are shown after the C code listing.

This is the C code for the example:

```
/* ===== SwiHookExample.c =====
 * This example demonstrates basic Swi hook usage */

#include <xdc/std.h>
#include <xdc/runtime/Error.h>
#include <xdc/runtime/System.h>
#include <xdc/runtime/Timestamp.h>

#include <ti/sysbios/BIOS.h>
#include <ti/sysbios/knl/Task.h>
#include <ti/sysbios/hal/Timer.h>
#include <ti/sysbios/knl/Swi.h>

Swi_Handle mySwi;
Int myHookSetId1, myHookSetId2;

/* HookSet 1 functions */
```

```
/* ===== myRegister1 =====
 * invoked during Swi module startup before main
 * for each HookSet */
Void myRegister1(Int hookSetId)
{
    System_printf("myRegister1: assigned hookSet Id = %d\n",
hookSetId);
    myHookSetId1 = hookSetId;
}

/* ===== myCreate1 =====
 * invoked during Swi_create for dynamically created Swis */
Void myCreate1(Swi_Handle swi, Error_Block *eb)
{
    Ptr pEnv;

    pEnv = Swi_getHookContext(swi, myHookSetId1);

    /* pEnv should be 0 at this point. If not, there's a bug. */
    System_printf("myCreate1: pEnv = 0x%x, time = %d\n", pEnv,
Timestamp_get32());
    Swi_setHookContext(swi, myHookSetId1, (Ptr)0xdead1);
}

/* ===== myReady1 =====
 * invoked when Swi is posted */
Void myReady1(Swi_Handle swi)
{
    Ptr pEnv;

    pEnv = Swi_getHookContext(swi, myHookSetId1);

    System_printf("myReady1: pEnv = 0x%x, time = %d\n", pEnv,
Timestamp_get32());
    Swi_setHookContext(swi, myHookSetId1, (Ptr)0xbeef1);
}
```

```
/* ===== myBegin1 =====
 * invoked just before Swi func is run */
Void myBegin1(Swi_Handle swi)
{
    Ptr pEnv;

    pEnv = Swi_getHookContext(swi, myHookSetId1);

    System_printf("myBegin1: pEnv = 0x%x, time = %d\n", pEnv,
                  Timestamp_get32());
    Swi_setHookContext(swi, myHookSetId1, (Ptr)0xfeeb1);
}

/* ===== myEnd1 =====
 * invoked after Swi func returns */
Void myEnd1(Swi_Handle swi)
{
    Ptr pEnv;

    pEnv = Swi_getHookContext(swi, myHookSetId1);

    System_printf("myEnd1: pEnv = 0x%x, time = %d\n", pEnv,
                  Timestamp_get32());
    Swi_setHookContext(swi, myHookSetId1, (Ptr)0xc0de1);
}

/* ===== myDelete1 =====
 * invoked upon Swi deletion */
Void myDelete1(Swi_Handle swi)
{
    Ptr pEnv;

    pEnv = Swi_getHookContext(swi, myHookSetId1);

    System_printf("myDelete1: pEnv = 0x%x, time = %d\n", pEnv,
                  Timestamp_get32());
}
```

```
/* HookSet 2 functions */

/* ===== myRegister2 =====
 * invoked during Swi module startup before main
 * for each HookSet */
Void myRegister2(Int hookSetId)
{
    System_printf("myRegister2: assigned hookSet Id = %d\n",
                  hookSetId);
    myHookSetId2 = hookSetId;
}

/* ===== myCreate2 =====
 * invoked during Swi_create for dynamically created Swis */
Void myCreate2(Swi_Handle swi, Error_Block *eb)
{
    Ptr pEnv;

    pEnv = Swi_getHookContext(swi, myHookSetId2);

    /* pEnv should be 0 at this point. If not, there's a bug. */
    System_printf("myCreate2: pEnv = 0x%x, time = %d\n", pEnv,
                  Timestamp_get32());
    Swi_setHookContext(swi, myHookSetId2, (Ptr)0xdead2);
}

/* ===== myReady2 =====
 * invoked when Swi is posted */
Void myReady2(Swi_Handle swi)
{
    Ptr pEnv;

    pEnv = Swi_getHookContext(swi, myHookSetId2);

    System_printf("myReady2: pEnv = 0x%x, time = %d\n", pEnv,
                  Timestamp_get32());
    Swi_setHookContext(swi, myHookSetId2, (Ptr)0xbeef2);
}
```

```
/* ===== myBegin2 =====
 * invoked just before Swi func is run */
Void myBegin2(Swi_Handle swi)
{
    Ptr pEnv;

    pEnv = Swi_getHookContext(swi, myHookSetId2);

    System_printf("myBegin2: pEnv = 0x%x, time = %d\n", pEnv,
                  Timestamp_get32());
    Swi_setHookContext(swi, myHookSetId2, (Ptr)0xfeeb2);
}

/* ===== myEnd2 =====
 * invoked after Swi func returns */
Void myEnd2(Swi_Handle swi)
{
    Ptr pEnv;

    pEnv = Swi_getHookContext(swi, myHookSetId2);

    System_printf("myEnd2: pEnv = 0x%x, time = %d\n", pEnv,
                  Timestamp_get32());
    Swi_setHookContext(swi, myHookSetId2, (Ptr)0xc0de2);
}

/* ===== myDelete2 =====
 * invoked upon Swi deletion */
Void myDelete2(Swi_Handle swi)
{
    Ptr pEnv;

    pEnv = Swi_getHookContext(swi, myHookSetId2);

    System_printf("myDelete2: pEnv = 0x%x, time = %d\n", pEnv,
                  Timestamp_get32());
}

/* ===== mySwiFunc ===== */
Void mySwiFunc(UArg arg0, UArg arg1)
{
    System_printf("Entering mySwi.\n");
}
```

```
/* ===== myTaskFunc ===== */
Void myTaskFunc(UArg arg0, UArg arg1)
{
    System_printf("Entering myTask.\n");

    System_printf("Posting mySwi.\n");
    Swi_post(mySwi);

    System_printf("Deleting mySwi.\n");
    Swi_delete(&mySwi);

    System_printf("myTask exiting ... \n");
}

/* ===== myIdleFunc ===== */
Void myIdleFunc()
{
    System_printf("Entering myIdleFunc().\n");
    System_exit(0);
}

/* ===== main ===== */
Int main(Int argc, Char* argv[])
{
    System_printf("Starting SwiHookExample... \n");

    /* Create mySwi with default params
     * to exercise Swi Hook Functions      */
    mySwi = Swi_create(mySwiFunc, NULL, NULL);

    BIOS_start();
    return (0);
}
```

This is the XDCtools configuration script for the example:

```
/* pull in Timestamp to print time in hook functions */
xdc.useModule('xdc.runtime.Timestamp');

/* Disable Clock so that ours is the
 * only Swi in the application */
var BIOS = xdc.useModule('ti.sysbios.BIOS');
BIOS.clockEnabled = false;

var Idle = xdc.useModule('ti.sysbios.knl.Idle');
Idle.addFunc('&myIdleFunc');

/* Create myTask with default task params */
var Task = xdc.useModule('ti.sysbios.knl.Task');
var taskParams = new Task.Params();
Program.global.myTask = Task.create('&myTaskFunc', taskParams);

/* Define and add two Swi Hook Sets */
var Swi = xdc.useModule("ti.sysbios.knl.Swi");

/* Hook Set 1 */
Swi.addHookSet({
    registerFxn: '&myRegister1',
    createFxn: '&myCreate1',
    readyFxn: '&myReady1',
    beginFxn: '&myBegin1',
    endFxn: '&myEnd1',
    deleteFxn: '&myDelete1'
});

/* Hook Set 2 */
Swi.addHookSet({
    registerFxn: '&myRegister2',
    createFxn: '&myCreate2',
    readyFxn: '&myReady2',
    beginFxn: '&myBegin2',
    endFxn: '&myEnd2',
    deleteFxn: '&myDelete2'
});
```

This is the output for the application:

```
myRegister1: assigned hookSet Id = 0
myRegister2: assigned hookSet Id = 1
Starting SwiHookExample...
myCreate1: pEnv = 0x0, time = 315
myCreate2: pEnv = 0x0, time = 650
Entering myTask.
Posting mySwi.
myReady1: pEnv = 0xdead1, time = 1275
myReady2: pEnv = 0xdead2, time = 1678
myBegin1: pEnv = 0xbeef1, time = 2093
myBegin2: pEnv = 0xbeef2, time = 2496
Entering mySwi.
myEnd1: pEnv = 0xfeeb1, time = 3033
myEnd2: pEnv = 0xfeeb2, time = 3421
Deleting mySwi.
myDelete1: pEnv = 0xc0de1, time = 3957
myDelete2: pEnv = 0xc0de2, time = 4366
myTask exiting ...
Entering myIdleFunc().
```

2.5 Tasks

SYS/BIOS task objects are threads that are managed by the Task module. Tasks have higher priority than the Idle Loop and lower priority than hardware and software interrupts.

The Task module dynamically schedules and preempts tasks based on the task's priority level and the task's current execution state. This ensures that the processor is always given to the highest priority thread that is ready to run. There are up to 32 priority levels available for tasks, with the default number of levels being 16. The maximum number of priority levels is 16 for MSP430 and C28x. The lowest priority level (0) is reserved for running the Idle Loop.

The Task module provides a set of functions that manipulate task objects. They access Task objects through handles of type `Task_Handle`.

The kernel maintains a copy of the processor registers for each task object. Each task has its own runtime stack for storing local variables as well as for further nesting of function calls. See Section 2.5.3 for information about task stack sizes.

All tasks executing within a single program share a common set of global variables, accessed according to the standard rules of scope defined for C functions.

Communication between the target and the SYS/BIOS Analysis Tools is performed in a Real-Time Analysis (RTA) task. The priority of this task is configurable and defaults to "1", the lowest priority. This ensures that the SYS/BIOS Analysis Tools do not interfere with higher-priority processing.

2.5.1 Creating Tasks

You can create Task objects either dynamically with a call to `Task_create()` or statically in the configuration. Tasks that you create dynamically can also be deleted during program execution.

2.5.1.1 *Creating and Deleting Tasks Dynamically*

You can spawn SYS/BIOS tasks by calling the function `Task_create()`, whose parameters include the address of a C function in which the new task begins its execution. The value returned by `Task_create()` is a handle of type `Task_Handle`, which you can then pass as an argument to other Task functions.

This C example creates a task:

```
Task_Params taskParams;

/* Create 1 task with priority 15 */
Task_Params_init(&taskParams);
taskParams.stackSize = 512;
taskParams.priority = 15;
Task_create((Task_FuncPtr)hiPriTask, &taskParams, &eb);
```

If NULL is passed instead of a pointer to an actual Task_Params struct, a default set of parameters is used. The "eb" is an error block that you can use to handle errors that may occur during Task object creation. See Section 2.5.3 for information about task stack sizes.

A task becomes active when it is created and preempts the currently running task if it has a higher priority.

The memory used by Task objects and stacks can be reclaimed by calling Task_delete(). Task_delete() removes the task from all internal queues and frees the task object and stack.

Any Semaphores or other resources held by the task are *not* released. Deleting a task that holds such resources is often an application design error, although not necessarily so. In most cases, such resources should be released prior to deleting the task. It is only safe to delete a Task that is either in the Terminated or Inactive State.

```
Void Task_delete(Task_Handle *task);
```

2.5.1.2 Creating Tasks Statically

You can also create tasks statically within a configuration script. The configuration allows you to set a number of properties for each task and for the Task Manager itself.

For a complete description of all Task properties, see the Task module in the "ti.sysbios.knl" package documentation in the online documentation. (For information on running online help, see Section 1.6.1, *Using the A PI Reference Help System*, page 1-10.)

While it is running, a task that was created statically behaves exactly the same as a task created with Task_create(). You cannot use the Task_delete() function to delete statically-created tasks. See the *XDCtools Consumer User's Guide* for a discussion of the benefits of creating objects statically.

The Task module automatically creates the Task_idle task and gives it the lowest task priority (0). It runs the functions defined for the Idle objects when no higher-priority Hwi, Swi, or Task is running.

When you configure tasks to have equal priority, they are scheduled in the order in which they are created in the configuration script. Tasks can have up to 32 priority levels with 16 being the default. The maximum number of priority levels is 16 for MSP430 and C28x. The highest level is the number of priorities defined minus 1, and the lowest is 0. The priority level of 0 is reserved for the system idle task. You cannot sort tasks within a single priority level by setting the order property.

If you want a task to be initially inactive, set its priority to -1. Such tasks are not scheduled to run until their priority is raised at runtime.

2.5.2 Task Execution States and Scheduling

Each Task object is always in one of four possible states of execution:

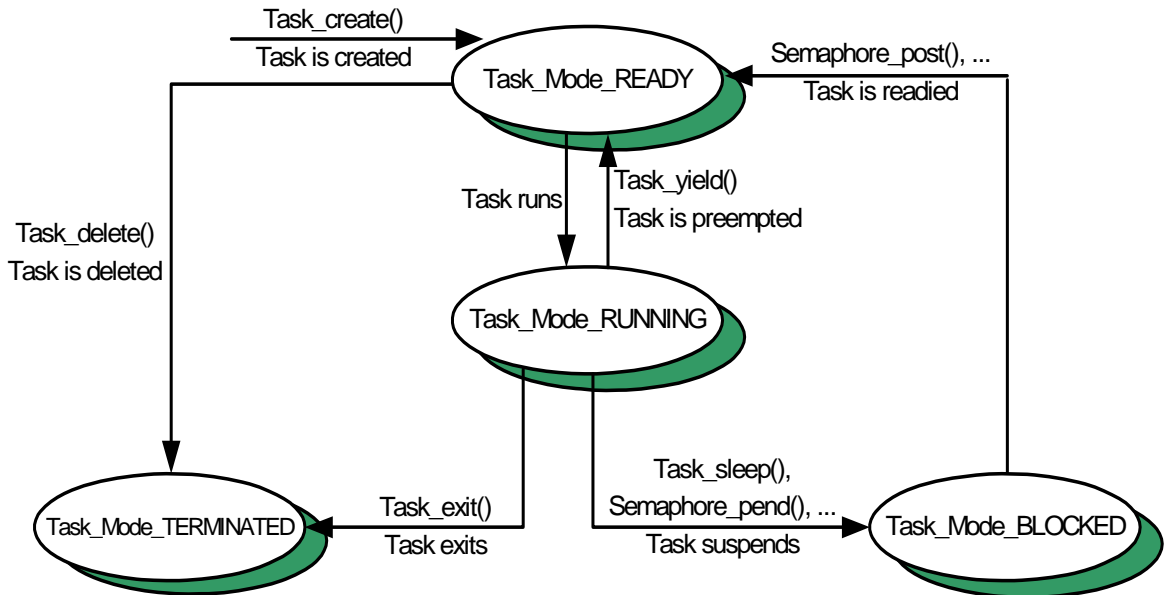

- Task_Mode_RUNNING**, which means the task is the one actually executing on the system's processor;
- Task_Mode_READY**, which means the task is scheduled for execution subject to processor availability;
- Task_Mode_BLOCKED**, which means the task cannot execute until a particular event occurs within the system; or
- Task_Mode_TERMINATED**, which means the task is "terminated" and does not execute again.
- Task_Mode_INACTIVE**, which means the task was created with priority equal to -1 and is in a pre-Ready state.

Tasks are scheduled for execution according to a priority level assigned by the application. There can be no more than one running task. As a rule, no ready task has a priority level greater than that of the currently running task, since Task preempts the running task in favor of the higher-priority ready task. Unlike many time-sharing operating systems that give each task its "fair share" of the processor, SYS/BIOS *immediately* preempts the current task whenever a task of higher priority becomes ready to run.

The maximum priority level is Task_numPriorities-1 (default=15; maximum=31). The minimum priority is 1. If the priority is less than 0, the task is barred from further execution until its priority is raised at a later time by another task. If the priority equals Task_numPriorities-1, the task cannot be preempted by another task. A highest-priority task can still call Semaphore_pend(), Task_sleep(), or some other blocking call to allow tasks of lower priority to run.

During the course of a program, each task's mode of execution can change for a number of reasons. Figure 2-7 shows how execution modes change.

Figure 2-7. Execution Mode Variations

Functions in the Task, Semaphore, Event, and Mailbox modules alter the execution state of task objects: blocking or terminating the currently running task, readying a previously suspended task, re-scheduling the current task, and so forth.

There is *one* task whose execution mode is Task_Mode_RUNNING. If all program tasks are blocked and no Hwi or Swi is running, Task executes the Task_idle task, whose priority is lower than all other tasks in the system. When a task is preempted by a Hwi or Swi, the task execution mode returned for that task by Task_stat() is still Task_Mode_RUNNING because the task will run when the preemption ends.

Note:

Do not make blocking calls, such as Semaphore_pend() or Task_sleep(), from within an Idle function. Doing so causes the application to terminate.

When the `Task_Mode_RUNNING` task transitions to any of the other three states, control switches to the highest-priority task that is ready to run (that is, whose mode is `Task_Mode_READY`). A `Task_Mode_RUNNING` task transitions to one of the other modes in the following ways:

- ❑ The running task becomes `Task_Mode_TERMINATED` by calling `Task_exit()`, which is automatically called if and when a task returns from its top-level function. After all tasks have returned, the Task Manager terminates program execution by calling `System_exit()` with a status code of 0.
- ❑ The running task becomes `Task_Mode_BLOCKED` when it calls a function (for example, `Semaphore_pend()` or `Task_sleep()`) that causes the current task to suspend its execution; tasks can move into this state when they are performing certain I/O operations, awaiting availability of some shared resource, or idling.
- ❑ The running task becomes `Task_Mode_READY` and is preempted whenever some other, higher-priority task becomes ready to run. `Task_setpri()` can cause this type of transition if the priority of the current task is no longer the highest in the system. A task can also use `Task_yield()` to yield to other tasks with the same priority. A task that yields becomes ready to run.

A task that is currently `Task_Mode_BLOCKED` transitions to the ready state in response to a particular event: completion of an I/O operation, availability of a shared resource, the elapse of a specified period of time, and so forth. By virtue of becoming `Task_Mode_READY`, this task is scheduled for execution according to its priority level; and, of course, this task immediately transitions to the running state if its priority is higher than the currently executing task. Task schedules tasks of equal priority on a first-come, first-served basis.

2.5.3 Task Stacks

The kernel maintains a copy of the processor registers for each Task object. Each Task has its own runtime stack for storing local variables as well as for further nesting of function calls.

You can specify the stack size separately for each Task object when you create the Task object statically or dynamically.

Each task stack must be large enough to handle both its normal function calls and two full interrupting Hwi contexts.

The following table shows the amount of task stack required to absorb the worst-case interrupt nesting. These numbers represent two full Hwi interrupt contexts plus space used by the task scheduler for its local variables. Additional nested interrupt contexts are pushed onto the common system stack.

Table 2–6 Task Stack Use by Target Family

Target Family	Stack Consumed	Units
M3	100	8-bit bytes
MSP430	52	8-bit bytes
MSP430X	96	8-bit bytes
MSP430X_small	52	8-bit bytes
C674	676	8-bit bytes
C64P	676	8-bit bytes
C64T	428	8-bit bytes
C28_float	123	16-bit words
C28_large	97	16-bit words
Arm9	184	8-bit bytes

When a Task is preempted, a task stack may be required to contain either two interrupting Hwi contexts (if the Task is preempted by a Hwi) or one interrupting Hwi context and one Task preemption context (if the Task is preempted by a higher-priority Task). Since the Hwi context is larger than the Task context, the numbers given are for two Hwi contexts. If a Task blocks, only those registers that a C function must save are saved to the task stack.

Another way to find the correct stack size is to make the stack size large and then use Code Composer Studio software to find the stack size actually used.

See Section 2.4.3 for information about system stack size.

2.5.4 Testing for Stack Overflow

When a task uses more memory than its stack has been allocated, it can write into an area of memory used by another task or data. This results in unpredictable and potentially fatal consequences. Therefore, a means of checking for stack overflow is useful.

By default, the Task module checks to see whether a Task stack has overflowed at each Task switch. To improve Task switching latency, you can disable this feature the `Task.checkStackFlag` property to `false`.

The function `Task_stat()` can be used to watch stack size. The structure returned by `Task_stat()` contains both the size of its stack and the maximum number of MAUs ever used on its stack, so this code segment could be used to warn of a nearly full stack:

```
Task_Stat statbuf;                               /* declare buffer */

Task_stat(Task_self(), &statbuf); /* call func to get status */
if (statbuf.used > (statbuf.stacksize * 9 / 10)) {
    Log_printf(&trace, "Over 90% of task's stack is in use.\n")
}
}
```

See the `Task_stat()` information in the "ti.sysbios.knl" package documentation in the online documentation.

You can use the Runtime Object Viewer (ROV) to examine run-time Task stack usage. For information, see Section 5.5.3.

2.5.5 Task Hooks

The Task module supports the following set of Hook functions:

- ❑ **Register.** A function called before any statically created Tasks are initialized at runtime. The register hook is called at boot time before `main()` and before interrupts are enabled.
- ❑ **Create.** A function called when a Task is created. This includes Tasks that are created statically and those created dynamically using `Task_create()` or `Task_construct()`. The Create hook is called outside of a `Task_disable/enable` block and before the task has been added to the ready list.
- ❑ **Ready.** A function called when a Task becomes ready to run. The ready hook is called from within a `Task_disable/enable` block with interrupts enabled.
- ❑ **Switch.** A function called just before a task switch occurs. The 'prev' and 'next' task handles are passed to the Switch hook. 'prev' is set to `NULL` for the initial task switch that occurs during SYS/BIOS startup. The Switch hook is called from within a `Task_disable/enable` block with interrupts enabled.
- ❑ **Exit.** A function called when a task exits using `Task_exit()`. The exit hook is passed the handle of the exiting task. The exit hook is called outside of

a Task_disable/enable block and before the task has been removed from the kernel lists.

- ❑ **Delete.** A function called when a task is deleted at runtime with Task_delete().

The following HookSet structure type definition encapsulates the hook functions supported by the Task module:

```
typedef struct Task_HookSet {
    Void (*registerFxn)(Int);           /* Register Hook */
    Void (*createFxn)(Handle, Error.Block *); /* Create Hook */
    Void (*readyFxn)(Handle);         /* Ready Hook */
    Void (*switchFxn)(Handle, Handle); /* Switch Hook */
    Void (*exitFxn)(Handle);          /* Exit Hook */
    Void (*deleteFxn)(Handle);        /* Delete Hook */
};
```

When more than one hook set is defined, the individual hook functions of a common type are invoked in hook ID order.

Task hook functions can only be configured statically.

2.5.5.1 Register Function

The Register function is provided to allow a hook set to store its corresponding hook ID. This ID can be passed to Task_setHookContext() and Task_getHookContext() to set or get hook-specific context. The Register function must be specified if the hook implementation needs to use Task_setHookContext() or Task_getHookContext().

The registerFxn function is called during system initialization before interrupts have been enabled.

The Register function has the following signature:

```
Void registerFxn(Int id);
```

2.5.5.2 Create and Delete Functions

The Create and Delete functions are called whenever a Task is created or deleted. The Create function is passed an Error_Block that is to be passed to Memory_alloc() for applications that require additional context storage space.

The createFxn and deleteFxn functions are called with interrupts enabled (unless called at boot time or from main()).

These functions have the following signatures.

```
Void createFxn(Task_Handle task, Error_Block *eb);
Void deleteFxn(Task_Handle task);
```

2.5.5.3 Switch Function

If a switch function is specified, it is invoked just before the new task is switched to. The switch function is called with interrupts enabled.

This function can be used for purposes such as saving/restoring additional task context (for example, external hardware registers), checking for task stack overflow, and monitoring the time used by each task.

The switchFxn has the following signature:

```
Void switchFxn(Task_Handle prev, Task_Handle next);
```

2.5.5.4 Ready Function

If a Ready Function is specified, it is invoked whenever a task is made ready to run. The Ready Function is called with interrupts enabled (unless called at boot time or from main()).

The readyFxn has the following signature:

```
Void readyFxn(Task_Handle task);
```

2.5.5.5 Exit Function

If an Exit Function is specified, it is invoked when a task exits (via call to Task_exit() or when a task returns from its' main function). The exitFxn is called with interrupts enabled.

The exitFxn has the following signature:

```
Void exitFxn(Task_Handle task);
```

2.5.5.6 Task Hooks Example

The following example application uses a single Task hook set. This example demonstrates how to read and write the Hook Context Pointer associated with each hook set.

The XDCtools configuration script and program output are shown after the C code listing.

This is the C code for the example:

```

/* ===== TaskHookExample.c =====
 * This example demonstrates basic task hook processing
 * operation for dynamically created tasks. */

#include <xdc/std.h>
#include <xdc/runtime/Error.h>
#include <xdc/runtime/Memory.h>
#include <xdc/runtime/System.h>
#include <xdc/runtime/Types.h>

#include <ti/sysbios/BIOS.h>
#include <ti/sysbios/knl/Task.h>

Task_Handle myTsk0, myTsk1, myTsk2;
Int myHookSetId, myHookSetId2;

/* HookSet functions */

/* ===== myRegister =====
 * invoked during Swi module startup before main()
 * for each HookSet */
Void myRegister(Int hookSetId)
{
    System_printf("myRegister: assigned HookSet Id = %d\n",
                  hookSetId);
    myHookSetId = hookSetId;
}

/* ===== myCreate =====
 * invoked during Task_create for dynamically
 * created Tasks */
Void myCreate(Task_Handle task, Error_Block *eb)
{
    String name;
    Ptr pEnv;

    name = Task_Handle_name(task);
    pEnv = Task_getHookContext(task, myHookSetId);

    System_printf("myCreate: task name = '%s', pEnv = 0x%x\n",
                  name, pEnv);
    Task_setHookContext(task, myHookSetId, (Ptr)0xdead);
}

```

```
/* ===== myReady =====
 * invoked when Task is made ready to run */
Void myReady(Task_Handle task)
{
    String name;
    Ptr pEnv;

    name = Task_Handle_name(task);
    pEnv = Task_getHookContext(task, myHookSetId);

    System_printf("myReady: task name = '%s', pEnv = 0x%x\n",
                  name, pEnv);
    Task_setHookContext(task, myHookSetId, (Ptr)0xc0de);
}

/* ===== mySwitch =====
 * invoked whenever a Task switch occurs/is made ready to run */
Void mySwitch(Task_Handle prev, Task_Handle next)
{
    String prevName;
    String nextName;
    Ptr pPrevEnv;
    Ptr pNextEnv;

    if (prev == NULL) {
        System_printf("mySwitch: ignoring dummy 1st prev Task\n");
    }
    else {
        prevName = Task_Handle_name(prev);
        pPrevEnv = Task_getHookContext(prev, myHookSetId);

        System_printf("mySwitch: prev name = '%s',
                      pPrevEnv = 0x%x\n", prevName, pPrevEnv);
        Task_setHookContext(prev, myHookSetId, (Ptr)0xcafec0de);
    }
    nextName = Task_Handle_name(next);
    pNextEnv = Task_getHookContext(next, myHookSetId);

    System_printf("          next name = '%s', pNextEnv = 0x%x\n",
                  nextName, pNextEnv);
    Task_setHookContext(next, myHookSetId, (Ptr)0xc001c0de);
}
```

```
/* ===== myExit =====
 * invoked whenever a Task calls Task_exit() or falls through
 * the bottom of its task function. */
Void myExit(Task_Handle task)
{
    Task_Handle curTask = task;
    String name;
    Ptr pEnv;

    name = Task_Handle_name(curTask);
    pEnv = Task_getHookContext(curTask, myHookSetId);

    System_printf("myExit: curTask name = '%s', pEnv = 0x%x\n",
                  name, pEnv);
    Task_setHookContext(curTask, myHookSetId, (Ptr)0xdeadbeef);
}

/* ===== myDelete =====
 * invoked upon Task deletion */
Void myDelete(Task_Handle task)
{
    String name;
    Ptr pEnv;

    name = Task_Handle_name(task);
    pEnv = Task_getHookContext(task, myHookSetId);

    System_printf("myDelete: task name = '%s', pEnv = 0x%x\n",
                  name, pEnv);
}

/* Define 3 identical tasks */
Void myTsk0Func(UArg arg0, UArg arg1)
{
    System_printf("myTsk0 Entering\n");
    System_printf("myTsk0 Calling Task_yield\n");
    Task_yield();
    System_printf("myTsk0 Exiting\n");
}
```

```
Void myTsk1Func(UArg arg0, UArg arg1)
{
    System_printf("myTsk1 Entering\n");
    System_printf("myTsk1 Calling Task_yield\n");
    Task_yield();
    System_printf("myTsk1 Exiting\n");
}

Void myTsk2Func(UArg arg0, UArg arg1)
{
    System_printf("myTsk2 Entering\n");
    System_printf("myTsk2 Calling Task_yield\n");
    Task_yield();
    System_printf("myTsk2 Exiting\n");
}

/* ===== main ===== */
Int main(Int argc, Char* argv[])
{
    Task_Params params;
    Task_Params_init(&params);

    params.instance->name = "myTsk0";
    myTsk0 = Task_create(myTsk0Func, &params, NULL);

    params.instance->name = "myTsk1";
    myTsk1 = Task_create(myTsk1Func, &params, NULL);

    params.instance->name = "myTsk2";
    myTsk2 = Task_create(myTsk2Func, &params, NULL);

    BIOS_start();
    return (0);
}

/* ===== myIdleFunc ===== */
Void myIdleFunc()
{
    System_printf("Entering idleFunc().\n");

    Task_delete(&myTsk0);
    Task_delete(&myTsk1);
    Task_delete(&myTsk2);

    System_exit(0);
}
```

The XDCtools configuration script is as follows:

```
/* Lots of System_printf() output requires a bigger bufSize */
SysMin = xdc.useModule('xdc.runtime.SysMin');
SysMin.bufSize = 4096;

var Idle = xdc.useModule('ti.sysbios.knl.Idle');
Idle.addFunc('&myIdleFunc');

var Task = xdc.useModule('ti.sysbios.knl.Task');

/* Enable instance names */
Task.common$.namedInstance = true;

/* Define and add one Task Hook Set */
Task.addHookSet({
    registerFxn: '&myRegister',
    createFxn: '&myCreate',
    readyFxn: '&myReady',
    switchFxn: '&mySwitch',
    exitFxn: '&myExit',
    deleteFxn: '&myDelete',
});
```

The program output is as follows:

```
myRegister: assigned HookSet Id = 0
myCreate: task name = 'ti.sysbios.knl.Task.IdleTask', pEnv = 0x0
myReady: task name = 'ti.sysbios.knl.Task.IdleTask', pEnv =
0xdead
myCreate: task name = 'myTsk0', pEnv = 0x0
myReady: task name = 'myTsk0', pEnv = 0xdead
myCreate: task name = 'myTsk1', pEnv = 0x0
myReady: task name = 'myTsk1', pEnv = 0xdead

2.5.6 Task Yielding for Time-Slice Scheduling

Example 2-1 demonstrates a time-slicing scheduling model that can be managed by a user. This model is preemptive and does not require any cooperation (that is, code) by the tasks. The tasks are programmed as if they were the only thread running. Although SYS/BIOS tasks of differing priorities can exist in any given application, the time-slicing model only applies to tasks of equal priority.

In this example, a periodic Clock object is configured to run a simple function that calls the `Task_yield()` function every 4 clock ticks. Another periodic Clock object is to run a simple function that calls the `Semaphore_post()` function every 16 milliseconds.

The output of the example code is shown after the code.

Example 2-1. Time-Slice Scheduling

```

/*
 * ===== slice.c =====
 * This example utilizes time-slice scheduling among three
 * tasks of equal priority. A fourth task of higher
 * priority periodically preempts execution.
 *
 * A periodic Clock object drives the time-slice scheduling.
 * Every 4 milliseconds, the Clock object calls Task_yield()
 * which forces the current task to relinquish access to
 * to the CPU.
 *
 * Because a task is always ready to run, this program
 * does not spend time in the idle loop. Calls to Idle_run()
 * are added to give time to the Idle loop functions
 * occasionally. The call to Idle_run() is within a
 * Task_disable(), Task_restore() block because the call
 * to Idle_run() is not reentrant.
 */

```

```
#include <xdc/std.h>
#include <xdc/runtime/System.h>

#include <ti/sysbios/BIOS.h>
#include <ti/sysbios/knl/Semaphore.h>
#include <ti/sysbios/knl/Clock.h>

{
    /* Call Semaphore_post every 16 ms */
    Semaphore_post(sem);
}
```

```
/* ===== task ===== */
Void task(UArg arg0, UArg arg1)
{
    Int time;
    Int prevtime = -1;
    UInt taskKey;

    /* While loop simulates work load of time-sharing tasks */
    while (1) {
        time = Clock_getTicks();

        /* print time once per clock tick */
        if (time >= prevtime + 1) {
            prevtime = time;
            System_printf("Task %d: time is %d\n",
                (Int)arg0, time);
        }

        /* check for rollover */
        if (prevtime > time) {
            prevtime = time;
        }

        /* Process the Idle Loop functions */
        taskKey = Task_disable();
        Idle_run();
        Task_restore(taskKey);
    }
}

/* ===== hiPriTask ===== */
Void hiPriTask(UArg arg0, UArg arg1)
{
    static Int numTimes = 0;

    while (1) {
        System_printf("hiPriTask here\n");
        if (++numTimes < 3) {
            Semaphore_pend(sem, BIOS_WAIT_FOREVER);
        }
        else {
            System_printf("Slice example ending.\n");
            System_exit(0);
        }
    }
}
```

The `System_printf()` output for this example is as follows:

```
Slice example started!  
hiPriTask here

Task 1: time is 31  
hiPriTask here  
Slice example ending.
```

2.6 The Idle Loop

The Idle Loop is the background thread of SYS/BIOS, which runs continuously when no Hwi, Swi, or Task is running. Any other thread can preempt the Idle Loop at any point.

The Idle Manager allows you to insert functions that execute within the Idle Loop. The Idle Loop runs the Idle functions you configured. Idle_loop calls the functions associated with each one of the Idle objects one at a time, and then starts over again in a continuous loop.

Idle threads all run at the same priority, sequentially. The functions are called in the same order in which they were created. An Idle function must run to completion before the next Idle function can start running. When the last idle function has completed, the Idle Loop starts the first Idle function again.

Idle Loop functions are often used to poll non-real-time devices that do not (or cannot) generate interrupts, monitor system status, or perform other background activities.

The Idle Loop is the thread with lowest priority in a SYS/BIOS application. The Idle Loop functions run only when no Hwis, Swis, or Tasks need to run.

The CPU load and thread load are computed in an Idle loop function. (Data transfer for between the target and the host is handled by a low-priority task.)

If you configure Task.enableIdleTask to be false, no Idle task is created and the Idle functions are not run. If you want a function to run when there are no other threads ready to run, you can specify such a function using Task.allBlockedFunc.

If you want the Idle Loop to run without creating a dedicated Idle task, you can disable Task.enableIdleTask and configure Task.allBlockedFunc as follows. These statements cause the Idle functions to be run using the stack of the last Task to pend.

```
Task.enableIdleTask = false;  
Task.allBlockedFunc = Idle.run;
```

2.7 Example Using Hwi, Swi, and Task Threads

This example depicts a stylized version of the SYS/BIOS Clock module design. It uses a combination of Hwi, Swi, and Task threads.

A periodic timer interrupt posts a Swi that processes the Clock object list. Each entry in the Clock object list has its own period and Clock function. When an object's period has expired, the Clock function is invoked and the period restarted.

Since there is no limit to the number of Clock objects that can be placed in the list and no way to determine the overhead of each Clock function, the length of time spent servicing all the Clock objects is non-deterministic. As such, servicing the Clock objects in the timer's Hwi thread is impractical. Using a Swi for this function is a relatively (as compared with using a Task) lightweight solution to this problem.

The XDCtools configuration script and program output are shown after the C code listing. This is the C code for the example:

```

/*
 * ===== HwiSwiTaskExample.c =====
 */

#include <xdc/std.h>
#include <xdc/runtime/System.h>

#include <ti/sysbios/BIOS.h>
#include <ti/sysbios/hal/Timer.h>
#include <ti/sysbios/knl/Semaphore.h>
#include <ti/sysbios/knl/Swi.h>
#include <ti/sysbios/knl/Task.h>
#include <ti/sdo/utils/List.h> /* List module in IPC */

#include <xdc/cfg/global.h>

typedef struct {
    List_Elem elem;
    UInt32 timeout;
    UInt32 period;
    Void (*fxn) (UArg);
    UArg arg;
} Clock_Object;

```

```
Clock_Object clk1, clk2;
Timer_Handle timer;
Semaphore_Handle sem;
Swi_Handle swi;
Task_Handle task;
List_Handle clockList;

/* Here on Timer interrupt */
Void hwiFxn(UArg arg)
{
    Swi_post(swi);
}

/* Swi thread to handle Timer interrupt */
Void swiFxn(UArg arg1, UArg arg2)
{
    List_Elem *elem;
    Clock_Object *obj;

    /* point to first clock object in the clockList */
    elem = List_next(clockList, NULL);

    /* service all the Clock Objects in the clockList */
    while (elem != NULL) {
        obj = (Clock_Object *)elem;

        /* decrement the timeout counter */
        obj->timeout -= 1;

        /* if period has expired, refresh the timeout
         * value and invoke the clock func */
        if (obj->timeout == 0) {
            obj->timeout = obj->period;
            (obj->fxn)(obj->arg);
        }

        /* advance to next clock object in clockList */
        elem = List_next(clockList, elem);
    }
}
```

```
/* Task thread pends on Semaphore posted by Clock thread */
Void taskFxn(UArg arg1, UArg arg2)
{
    System_printf("In taskFxn pending on Sempahore.\n");
    Semaphore_pend(sem, BIOS_WAIT_FOREVER);
    System_printf("In taskFxn returned from Sempahore.\n");
    System_exit(0);
}

/* First Clock function, invoked every 5 timer interrupts */
Void clk1Fxn(UArg arg)
{
    System_printf("In clk1Fxn, arg = %d.\n", arg);
    clk1.arg++;
}

/* Second Clock function, invoked every 20 timer interrupts */
Void clk2Fxn(UArg sem)
{
    System_printf("In clk2Fxn, posting Semaphore.\n");
    Semaphore_post((Semaphore_Object *)sem);
}

/* main() */
Int main(Int argc, char* argv[])
{
    Timer_Params timerParams;
    Task_Params taskParams;

    System_printf("Starting HwiSwiTask example.\n");

    Timer_Params_init(&timerParams);
    Task_Params_init(&taskParams);

    /* Create a Swi with default priority (15).
     * Swi handler is 'swiFxn' which runs as a Swi thread. */
    swi = Swi_create(swiFxn, NULL, NULL);

    /* Create a Task with priority 3.
     * Task function is 'taskFxn' which runs as a Task thread. */
    taskParams.priority = 3;
    task = Task_create(taskFxn, &taskParams, NULL);

    /* Create a binary Semaphore for example task to pend on */
    sem = Semaphore_create(0, NULL, NULL);
}
```

```
/* Create a List to hold the Clock Objects on */
clockList = List_create(NULL, NULL);

/* setup clk1 to go off every 5 timer interrupts. */
clk1.fxn = clk1Fxn;
clk1.period = 5;
clk1.timeout = 5;
clk1.arg = 1;
/* add the Clock object to the clockList */
List_put(clockList, &clk1.elem);

/* setup clk2 to go off every 20 timer interrupts. */
clk2.fxn = clk2Fxn;
clk2.period = 20;
clk2.timeout = 20;
clk2.arg = (UArg)sem;
/* add the Clock object to the clockList */
List_put(clockList, &clk2.elem);

/* Configure a periodic interrupt using any available Timer
 * with a 1000 microsecond (1ms) interrupt period.
 *
 * The Timer interrupt will be handled by 'hwiFxn' which
 * will run as a Hwi thread.
 */
timerParams.period = 1000;
timer = Timer_create(Timer_ANY, hwiFxn, &timerParams, NULL);

BIOS_start();

return(0);
}
```

The XDCtools configuration script is as follows:

```

/*
 * ===== HwiSwiTaskExample.cfg =====
 */

/* Configure System to use SysMin */
System = xdc.useModule('xdc.runtime.System');
System.SupportProxy = xdc.useModule('xdc.runtime.SysMin')

/* Use HeapMem for default heap manager and give it 8192
 * bytes to work with */
var Memory = xdc.useModule('xdc.runtime.Memory');
var HeapMem = xdc.useModule('ti.sysbios.heaps.HeapMem');

var heapParams = new HeapMem.Params;
heapParams.size = 8192;

Memory.defaultHeapInstance = HeapMem.create(heapParams);

/* Pull in Timer, Semaphore, Swi, Task, and List modules
 * used in this example. */
xdc.useModule('ti.sysbios.hal.Timer');
xdc.useModule('ti.sysbios.knl.Semaphore');
xdc.useModule('ti.sysbios.knl.Swi');
xdc.useModule('ti.sysbios.knl.Task');
xdc.useModule('ti.sdo.utils.List'); /* List module in IPC */

```

The program output is as follows:

```

Starting HwiSwiTask example.
In taskFxn pending on Semaphore.
In clk1Fxn, arg = 1.
In clk1Fxn, arg = 2.
In clk1Fxn, arg = 3.
In clk1Fxn, arg = 4.
In clk2Fxn, posting Semaphore.
In taskFxn returned from Semaphore

```

Synchronization Modules

This chapter describes modules that can be used to synchronize access to shared resources.

Topic	Page
3.1 Semaphores	3-2
3.2 Event Module	3-8
3.3 Gates	3-14
3.4 Mailboxes	3-18

3.1 Semaphores

SYS/BIOS provides a fundamental set of functions for inter-task synchronization and communication based upon *semaphores*. Semaphores are often used to coordinate access to a shared resource among a set of competing tasks. The Semaphore module provides functions that manipulate semaphore objects accessed through handles of type Semaphore_Handle.

Semaphore objects can be declared as either counting or binary semaphores. They can be used for task synchronization and mutual exclusion. The same APIs are used for both counting and binary semaphores.

Binary semaphores are either available or unavailable. Their value cannot be incremented beyond 1. Thus, they should be used for coordinating access to a shared resource by a maximum of two tasks. Binary semaphores provide better performance than counting semaphores.

Counting semaphores keep an internal count of the number of corresponding resources available. When count is greater than 0, tasks do not block when acquiring a semaphore. The maximum count value for a semaphores plus one is the number of tasks a counting semaphore can coordinate.

To configure the type of semaphore, use the following configuration parameter:

```
config Mode mode = Mode_COUNTING;
```

The functions Semaphore_create() and Semaphore_delete() are used to create and delete semaphore objects, respectively, as shown in Example 3-1. You can also create semaphore objects statically. See the *XDCtools Consumer User's Guide* for a discussion of the benefits of creating objects statically.

Example 3-1. Creating and Deleting a Semaphore

```
Semaphore_Handle Semaphore_create(Uns          count,  
                                 Semaphore_Params *attrs);  
  
Void Semaphore_delete(Semaphore_Handle *sem);
```

The semaphore count is initialized to count when it is created. In general, count is set to the number of resources that the semaphore is synchronizing.

Semaphore_pend() waits for a semaphore. If the semaphore count is greater than 0, Semaphore_pend() simply decrements the count and returns. Otherwise, Semaphore_pend() waits for the semaphore to be posted by Semaphore_post().

The timeout parameter to `Semaphore_pend()`, as shown in Example 3-2, allows the task to wait until a timeout, to wait indefinitely (`BIOS_WAIT_FOREVER`), or to not wait at all (`BIOS_NO_WAIT`). `Semaphore_pend()`'s return value is used to indicate if the semaphore was acquired successfully.

Example 3-2. Setting a Timeout with `Semaphore_pend()`

```
Bool Semaphore_pend(Semaphore_Handle sem,
                   UInt             timeout);
```

Example 3-3 shows `Semaphore_post()`, which is used to signal a semaphore. If a task is waiting for the semaphore, `Semaphore_post()` removes the task from the semaphore queue and puts it on the ready queue. If no tasks are waiting, `Semaphore_post()` simply increments the semaphore count and returns.

Example 3-3. Signaling a Semaphore with `Semaphore_post()`

```
Void Semaphore_post(Semaphore_Handle sem);
```

3.1.1 Semaphore Example

Example 3-4 provides sample code for three writer tasks that create unique messages and place them on a list for one reader task. The writer tasks call `Semaphore_post()` to indicate that another message has been put on the list. The reader task calls `Semaphore_pend()` to wait for messages. `Semaphore_pend()` returns only when a message is available on the list. The reader task prints the message using the `System_printf()` function.

The three writer tasks, a reader task, a semaphore, and a list in this example program were created statically as follows:

```
Program.system = xdc.useModule('xdc.runtime.SysMin');

var Sem = xdc.useModule('ti.sysbios.knl.Semaphore');
Program.global.sem = Sem.create(0);
Program.global.sem.mode = Sem.Mode_COUNTING;

var Task = xdc.useModule('ti.sysbios.knl.Task');
Task.idleTaskVitalTaskFlag = false;
var reader = Task.create('&reader');
reader.priority = 5;

var writer0 = Task.create('&writer');
writer0.priority = 3;
writer0.arg0 = 0;
```

```
var writer1 = Task.create('&writer');
writer1.priority = 3;
writer1.arg0 = 1;

var writer2 = Task.create('&writer');
writer2.priority = 3;
writer2.arg0 = 2;

/* uses List module in IPC distribution */
var List = xdc.useModule('ti.sdo.utils.List');
Program.global.msgList = List.create();
Program.global.freeList = List.create();
```

Since this program employs multiple tasks, a counting semaphore is used to synchronize access to the list. Figure 3-1 provides a view of the results from Example 3-3. Though the three writer tasks are scheduled first, the messages are read as soon as they have been put on the list, because the reader's task priority is higher than that of the writer.

Example 3-4. Semaphore Example Using Three Writer Tasks

```
/* ===== semtest.c ===== */
#include <xdc/std.h>
#include <xdc/runtime/Memory.h>
#include <xdc/runtime/System.h>
#include <ti/sysbios/BIOS.h>
#include <ti/sdo/utils/List.h>          /* List module in IPC */
#include <ti/sysbios/knl/Semaphore.h>
#include <ti/sysbios/knl/Task.h>

/* Config Tool */
typedef struct MsgObj {
    List_Elem elem;    /* first field for List */
    Int id;           /* writer task id */
    Char val;         /* message value */
} MsgObj, *Msg;

Void reader();
Void writer();
```

```

/* The following objects are created statically. */
extern Semaphore_Handle sem;
extern List_Handle msgList;
extern List_Handle freeList;

/* ===== main ===== */
Int main(Int argc, Char* argv[])
{
    Int i;
    MsgObj *msg;

    msg = (MsgObj *) Memory_alloc(NULL, NUMMSGS * sizeof(MsgObj),
                                   0, NULL);

    /* Put all messages on freeList */
    for (i = 0; i < NUMMSGS; msg++, i++) {
        List_put(freeList, (List_Elem *) msg);
    }
    BIOS_start();
    System_exit(0);
    return(0);
}

/* ===== reader ===== */
Void reader()
{
    Msg msg;
    Int i;
    for (i = 0; i < NUMMSGS * NUMWRITERS; i++) {
        /* Wait for semaphore to be posted by writer(). */
        Semaphore_pend(sem, BIOS_WAIT_FOREVER);

        /* get message */
        msg = List_get(msgList);
        /* print value */
        System_printf("read '%c' from (%d).\n", msg->val,
                      msg->id);
        /* free msg */
        List_put(freeList, (List_Elem *) msg);
    }
    System_printf("reader done.\n");
}

```

```
/* ===== writer ===== */
Void writer(Int id)
{
    Msg msg;
    Int i;

    for (i = 0; i < NUMMSGs; i++) {
        /* Get msg from the free list. Since reader is higher
         * priority and only blocks on sem, list is never
         * empty. */
        msg = List_get(freeList);

        /* fill in value */
        msg->id = id;
        msg->val = (i & 0xf) + 'a';
        System_printf("(%d) writing '%c' ...\\n", id, msg->val);

        /* put message */
        List_put(msgList, (List_Elem *) msg);

        /* post semaphore */
        Semaphore_post(sem);
    }

    System_printf("writer (%d) done.\\n", id);
}
```

reader done.
writer (2) done.
```

3.2 Event Module

Events provide a means for communicating between and synchronizing threads. They are similar to Semaphores (see Section 3.1), except that they allow you to specify multiple conditions ("events") that must occur before the waiting thread returns.

An Event instance is used with calls to "pend" and "post", just as for a Semaphore. However, calls to `Event_pend()` additionally specify which events to wait for, and calls to `Event_post()` specify which events are being posted.

Note: Only a single Task can pend on an Event object at a time.

A single Event instance can manage up to 32 events, each represented by an event ID. Event IDs are simply bit masks that correspond to a unique event managed by the Event object.

Each Event behaves like a binary semaphore.

A call to `Event_pend()` takes an "andMask" and an "orMask". The andMask consists of the event IDs of all the events that must occur, and the orMask consists of the event IDs of any events of which only one must occur.

As with Semaphores, a call to `Event_pend()` takes a timeout value and returns 0 if the call times out. If a call to `Event_pend()` is successful, it returns a mask of the "consumed" events—that is, the events that occurred to satisfy the call to `Event_pend()`. The task is then responsible for handling ALL of the consumed events.

Only Tasks can call `Event_pend()`, whereas Hwis, Swis, and other Tasks can all call `Event_post()`.

The `Event_pend()` prototype is as follows:

```
UInt Event_pend(Event_Handle event,
                UInt         andMask,
                UInt         orMask,
                UInt         timeout);
```

The `Event_post()` prototype is as follows:

```
Void Event_post(Event_Handle event,
                UInt         eventIds);
```

Configuration example: These XDCtools configuration statements create an event statically. The Event object has an Event_Handle named "myEvent".

```
var Event = xdc.useModule("ti.sysbios.knl.Event");
Program.global.myEvent = Event.create();
```

Runtime example: The following C code creates an Event object with an Event_Handle named "myEvent".

```
Event_Handle myEvent;

/* Default instance configuration params and NULL Error Block */
myEvent = Event_create(NULL, NULL);
```

Runtime example: The following C code blocks on an event. It wakes the task only when both events 0 and 6 have occurred. It sets the andMask to enable both Event_Id_00 and Event_Id_06. It sets the orMask to Event_Id_NONE.

```
Event_pend(myEvent, (Event_Id_00 + Event_Id_06), Event_Id_NONE,
           BIOS_WAIT_FOREVER);
```

Runtime example: The following C code has a call to Event_post() to signal which events have occurred. The eventMask should contain the IDs of the events that are being posted.

```
Event_post(myEvent, Event_Id_00);
```

Runtime Example: The following C code example shows a task that provides the background processing required for three Interrupt Service Routines:

```
Event_Handle myEvent;
```

```
main()
```

```
{  
    /* create an Event object. All events are binary */  
    myEvent = Event_create(NULL, NULL);  
}
```

```
isr0()
```

```
{  
    ...  
    Event_post(myEvent, Event_Id_00);  
    ...  
}
```

```
isr1()
```

```
{  
    ...  
    Event_post(myEvent, Event_Id_01);  
    ...  
}
```

```
isr2()
```

```
{  
    ...  
    Event_post(myEvent, Event_Id_02);  
    ...  
}
```

```

task()
{
    UInt events;

    while (TRUE) {
        /* Wait for ANY of the ISR events to be posted */
        events = Event_pend(myEvent, Event_Id_NONE,
            Event_Id_00 + Event_Id_01 + Event_Id_02,
            BIOS_WAIT_FOREVER);

        /* Process all the events that have occurred */
        if (events & Event_Id_00) {
            processISR0();
        }
        if (events & Event_Id_01) {
            processISR1();
        }
        if (events & Event_Id_02) {
            processISR2();
        }
    }
}

```

3.2.1 Implicitly Posted Events

In addition to supporting the explicit posting of events through the `Event_post()` API, some SYS/BIOS objects support implicit posting of events associated with their objects. For example, a Mailbox can be configured to post an associated event whenever a message is available (that is, whenever `Mailbox_post()` is called) thus allowing a task to block while waiting for a Mailbox message and/or some other event to occur.

Mailbox and Semaphore objects currently support the posting of events associated with their resources becoming available.

SYS/BIOS objects that support implicit event posting must be configured with an event object and event ID when created. You can decide which event ID to associate with the specific resource availability signal (that is, a message available in Mailbox, room available in Mailbox, or Semaphore available).

Note: As mentioned earlier, only one Task can pend on an Event object at a time. Consequently, SYS/BIOS objects that are configured for implicit event posting should only be waited on by a single Task at a time.

When `Event_pend()` is used to acquire a resource from implicitly posting objects, the `BIOS_NO_WAIT` timeout parameter should be used to subsequently retrieve the resource from the object.

Runtime example: The following C code example shows a task processing the messages posted to a Mailbox message as well as performing an ISR's post-processing requirements.

```
Event_Handle myEvent;
Mailbox_Handle mbox;

typedef struct msg {
    UInt id;
    Char buf[10];
}

main()
{
    Mailbox_Params mboxParams;

    myEvent = Event_create(NULL, NULL);
    Mailbox_Params_init(&mboxParams);
    mboxParams.notEmptyEvent = myEvent;

    /* Assign Event_Id_00 to Mailbox "not empty" event */
    mboxParams.notEmptyEventId = Event_Id_00;
    mbox = Mailbox_create(sizeof(msg), 50, &mboxParams, NULL);

    /* Mailbox_create() sets Mailbox's notEmptyEvent to
     * counting mode and initial count = 50 */
}
```

```
writerTask()
{
    ...
    Mailbox_post(mbox, &msgA, FOREVER);
    /* implicitly posts Event_Id_00 to myEvent */
    ...
}

isr()
{
    Event_post(myEvent, Event_Id_01);
}

readerTask()
{
    while (TRUE) { /* Wait for either ISR or Mailbox message */
        events = Event_pend(myEvent,
                           Event_Id_NONE,          /* andMask = 0 */
                           Event_Id_00 + Event_Id_01, /* orMask */
                           BIOS_WAIT_FOREVER);      /* timeout */
        if (events & Event_Id_00) {
            /* Get the posted message.
             * Mailbox_pend() will not block since Event_pend()
             * has guaranteed that a message is available.
             * Notice that the special BIOS_NO_WAIT
             * parameter tells Mailbox that Event_pend()
             * was used to acquire the available message.
             */
            Mailbox_pend(mbox, &msgB, BIOS_NO_WAIT);
            processMsg(&msgB);
        }
        if (events & Event_Id_01) {
            processISR();
        }
    }
}
```

3.3 Gates

A "Gate" is a module that implements the `IGateProvider` interface. Gates are devices for preventing concurrent accesses to critical regions of code. The various Gate implementations differ in how they attempt to lock the critical regions.

Since `xdc.runtime.Gate` is provided by XDCtools, the base module is documented in the online help and the RTSC-pedia wiki. Implementations of Gates provided by SYS/BIOS are discussed here.

Threads can be preempted by other threads of higher priority, and some sections of code need to be completed by one thread before they can be executed by another thread. Code that modifies a linked list is a common example of a critical region that may need to be protected by a Gate.

Gates generally work by either disabling some level of preemption such as disabling task switching or even hardware interrupts, or by using a binary semaphore.

All Gate implementations support nesting through the use of a "key". For Gates that function by disabling preemption, it is possible that multiple threads would call `Gate_enter()`, but preemption should not be restored until all of the threads have called `Gate_leave()`. This functionality is provided through the use of a key. A call to `Gate_enter()` returns a key that must then be passed back to `Gate_leave()`. Only the outermost call to `Gate_enter()` returns the correct key for restoring preemption. (The actual module name for the implementation is used instead of "Gate" in the function name.)

Runtime example: The following C code protects a critical region with a Gate. This example uses a `GateHwi`, which disables and enables interrupts as the locking mechanism.

```
UInt gateKey;
GateHwi_Handle gateHwi;
GateHwi_Params prms;
GateHwi_Params_init(&prms);

gateHwi = GateHwi_create(&prms, NULL);

/* Simultaneous operations on a List by multiple threads could
 * corrupt the List structure, so modifications to the List
 * are protected with a Gate. */
gateKey = GateHwi_enter(gateHwi);
List_get(myList);
GateHwi_leave(gateHwi, gateKey);
```

3.3.1 Preemption-Based Gate Implementations

The following implementations of gates use some form of preemption disabling:

- ❑ `ti.sysbios.gates.GateHwi`
- ❑ `ti.sysbios.gates.GateSwi`
- ❑ `ti.sysbios.gates.GateTask`

3.3.1.1 *GateHwi*

`GateHwi` disables and enables interrupts as the locking mechanism. Such a gate guarantees exclusive access to the CPU. This gate can be used when the critical region is shared by Task, Swi, or Hwi threads.

The duration between the enter and leave should be as short as possible to minimize Hwi latency.

3.3.1.2 *GateSwi*

`GateSwi` disables and enables software interrupts as the locking mechanism. This gate can be used when the critical region is shared by Swi or Task threads. This gate cannot be used by a Hwi thread.

The duration between the enter and leave should be as short as possible to minimize Swi latency.

3.3.1.3 *GateTask*

`GateTask` disables and enables tasks as the locking mechanism. This gate can be used when the critical region is shared by Task threads. This gate cannot be used by a Hwi or Swi thread.

The duration between the enter and leave should be as short as possible to minimize Task latency.

3.3.2 Semaphore-Based Gate Implementations

The following implementations of gates use a semaphore:

- ❑ `ti.sysbios.gates.GateMutex`
- ❑ `ti.sysbios.gates.GateMutexPri`

3.3.2.1 GateMutex

GateMutex uses a binary Semaphore as the locking mechanism. Each GateMutex instance has its own unique Semaphore. Because this gate can potentially block, it should not be used a Swi or Hwi thread, and should only be used by Task threads.

3.3.2.2 GateMutexPri

GateMutexPri is a mutex Gate (it can only be held by one thread at a time) that implements "priority inheritance" in order to prevent priority inversion. Priority inversion occurs when a high-priority Task has its priority effectively "inverted" because it is waiting on a Gate held by a lower-priority Task. Issues and solutions for priority inversion are described in Section 3.3.3.

Configuration example: The following example specifies a GateType to be used by HeapMem. (See section 5.8.1, *HeapMem* for further discussion.)

```
var GateMutexPri = xdc.useModule('ti.sysbios.gates.GateMutexPri');
var HeapMem = xdc.useModule('ti.sysbios.heaps.HeapMem');

HeapMem.common$.gate = GateMutexPri.create();
```

3.3.3 Priority Inversion

The following example shows the problem of priority inversion. A system has three tasks—Low, Med, and High—each with the priority suggested by its name. Task Low runs first and acquires the gate. Task High is scheduled and preempts Low. Task High tries to acquire the gate, and waits on it. Next, task Med is scheduled and preempts task Low. Now task High must wait for both task Med and task Low to finish before it can continue. In this situation, task Low has, in effect, lowered task High's priority to that of Low.

Solution: Priority Inheritance

To guard against priority inversion, GateMutexPri implements priority inheritance. When task High tries to acquire a gate that is owned by task Low, task Low's priority is temporarily raised to that of High, as long as High is waiting on the gate. So, task High "donates" its priority to task Low.

When multiple tasks wait on the gate, the gate owner receives the highest priority of any of the tasks waiting on the gate.

Caveats

Priority inheritance is not a complete guard against priority inversion. Tasks only donate their priority on the call to enter a gate, so if a task has its priority raised while waiting on a gate, that priority is not carried through to the gate owner.

This can occur in situations involving multiple gates. For example, a system has four tasks: VeryLow, Low, Med, and High, each with the priority suggested by its name. Task VeryLow runs first and acquires gate A. Task Low runs next and acquires gate B, then waits on gate A. Task High runs and waits on gate B. Task High has donated its priority to task Low, but Low is blocked on VeryLow, so priority inversion occurs despite the use of the gate. The solution to this problem is to design around it. If gate A may be needed by a high-priority, time-critical task, then it should be a design rule that no task holds this gate for a long time or blocks while holding this gate.

When multiple tasks wait on this gate, they receive the gate in order of priority (higher-priority tasks receive the gate first). This is because the list of tasks waiting on a GateMutexPri is sorted by priority, not FIFO.

Calls to GateMutexPri_enter() may block, so this gate can only be used in the task context.

GateMutexPri has non-deterministic calls because it keeps the list of waiting tasks sorted by priority.

3.4 Mailboxes

The `ti.sysbios.knl.Mailbox` module provides a set of functions to manage mailboxes. Mailboxes can be used to pass buffers from one task to another on the same processor.

A Mailbox instance can be used by multiple readers and writers.

The Mailbox module copies the buffer to fixed-size internal buffers. The size and number of these buffers are specified when a Mailbox instance is created (or constructed). A copy is done when a buffer is sent via `Mailbox_post()`. Another copy occurs when the buffer is retrieved via a `Mailbox_pend()`.

`Mailbox_create()` and `Mailbox_delete()` are used to create and delete mailboxes, respectively. You can also create mailbox objects statically. See the *XDCtools Consumer User's Guide* for a discussion of the benefits of creating objects statically.

Mailboxes can be used to ensure that the flow of incoming buffers does not exceed the ability of the system to process those buffers. The examples given later in this section illustrate just such a scheme.

You specify the number of internal mailbox buffers and size of each of these buffers when you create a mailbox. Since the size is specified when you create the Mailbox, all buffers sent and received with the Mailbox instance must be of this same size.

```
Mailbox_Handle Mailbox_create(SizeT          bufsize,  
                             UInt          numBufs,  
                             Mailbox_Params *params,  
                             Error_Block   *eb)
```

```
Void Mailbox_delete(Mailbox_Handle *handle);
```

`Mailbox_pend()` is used to read a buffer from a mailbox. If no buffer is available (that is, the mailbox is empty), `Mailbox_pend()` blocks. The timeout parameter allows the task to wait until a timeout, to wait indefinitely (`BIOS_WAIT_FOREVER`), or to not wait at all (`BIOS_NO_WAIT`). The unit of time is system clock ticks.

```
Bool Mailbox_pend(Mailbox_Handle handle,  
                 Ptr          buf,  
                 UInt          timeout);
```

`Mailbox_post()` is used to post a buffer to the mailbox. If no buffer slots are available (that is, the mailbox is full), `Mailbox_post()` blocks. The timeout parameter allows the task to wait until a timeout, to wait indefinitely (`BIOS_WAIT_FOREVER`), or to not wait at all (`BIOS_NO_WAIT`).

```
Bool Mailbox_post (Mailbox_Handle handle,  
                  Ptr          buf,  
                  UInt         timeout);
```

Mailbox provides configuration parameters to allow you to associate events with a mailbox. This allows you to wait on a mailbox message and another event at the same time. Mailbox provides two configuration parameters to support events for the reader(s) of the mailbox—`notEmptyEvent` and `notEmptyEventId`. These allow a mailbox reader to use an event object to wait for the mailbox message. Mailbox also provides two configuration parameters for the mailbox writer(s)—`notFullEvent` and `notFullEventId`. These allow mailbox writers to use an event object to wait for room in the mailbox.

When using events, a thread calls `Event_pend()` and waits on several events. Upon returning from `Event_pend()`, the thread must call `Mailbox_pend()` or `Mailbox_post()`—depending on whether it is a writer or a reader—with a special timeout value of `BIOS_EVENT_ACQUIRED`. This timeout value allows the thread to get/put the message into the mailbox. This special timeout value is necessary for correct operation of the mailbox when using Events.

Timing Services

This chapter describes modules that can be used for timing purposes.

Topic	Page
4.1 Overview of Timing Services	4-2
4.2 Clock	4-2
4.3 Timer Module	4-6
4.4 Timestamp Module	4-6

4.1 Overview of Timing Services

Several modules are involved in timekeeping and clock-related services within SYS/BIOS and XDCtools:

- ❑ **The `ti.sysbios.knl.Clock` module** is responsible for the periodic system tick that the kernel uses to keep track of time. All SYS/BIOS APIs that expect a timeout parameter interpret the timeout in terms of Clock ticks. The Clock module is used to schedule functions that run at intervals specified in clock ticks. By default, the Clock module uses the `hal.Timer` module to get a hardware-based tick. Alternately, the Clock module can be configured to use an application-provided tick source. See Section 4.2 for details. (The Clock module replaces both the CLK and PRD modules in earlier versions of DSP/BIOS.)
- ❑ **The `ti.sysbios.hal.Timer` module** provides a standard interface for using timer peripherals. It hides any target/device-specific characteristics of the timer peripherals. Target/device-specific properties for timers are supported by the `ti.sysbios.family.xxx.Timer` modules (for example, `ti.sysbios.family.c64.Timer`). You can use the Timer module to select a timer that calls a `tickFxn` when the timer expires. See Section 4.3 and Section 6.3 for details.
- ❑ **The `xdc.runtime.Timestamp` module** provides simple timestamping services for benchmarking code and adding timestamps to logs. This module uses a target/device-specific `TimestampProvider` in SYS/BIOS to control how timestamping is implemented. See Section 4.4 for details.

4.2 Clock

The `ti.sysbios.knl.Clock` module is responsible for the periodic system tick that the kernel uses to keep track of time. All SYS/BIOS APIs that expect a timeout parameter interpret the timeout in terms of Clock ticks.

The Clock module, by default, uses the `ti.sysbios.hal.Timer` module to create a timer to generate the system tick, which is basically a periodic call to `Clock_tick()`. See Section 4.3 for more about the Timer module.

The Clock module can be configured not to use the timer with either of the following configuration statements:

```
ti.sysbios.knl.Clock.tickSource = Clock.tickSource_USER
or
ti.sysbios.knl.Clock.tickSource = Clock.tickSource_NULL
```

The period for the system tick is set by the configuration parameter `Clock.tickPeriod`. This is set in microseconds.

The `Clock_tick()` and the tick period are used as follows:

- ❑ **If the tickSource is `Clock.tickSource_TIMER`** (the default), Clock uses `ti.sysbios.hal.Timer` to create a timer to generate the system tick, which is basically a periodic call to `Clock_tick()`. Clock uses `Clock.tickPeriod` to create the timer. `Clock.timerId` can be changed to make Clock use a different timer.
- ❑ **If the tickSource is `Clock.tickSource_USER`**, then your application must call `Clock_tick()` from a user interrupt and set the tickPeriod to the approximate frequency of the user interrupt in microseconds.
- ❑ **If the tickSource is `Clock.tickSource_NULL`**, you cannot call any SYS/BIOS APIs with a timeout value and cannot call any Clock APIs. You can still use the Task module but you cannot call APIs that require a timeout, for example, `Task_sleep()`. `Clock.tickPeriod` values is not valid in this configuration.

`Clock_getTicks()` gets the number of Clock ticks that have occurred since startup. The value returned wraps back to zero after it reaches the maximum value that can be stored in 32 bits.

The Clock module provides APIs to start, stop and reconfigure the tick. These APIs allow you to make frequency changes at runtime. These three APIs are not reentrant and gates need to be used to protect them.

- ❑ **`Clock_tickStop()`** stops the timer used to generate the Clock tick by calling `Timer_stop()`.
- ❑ **`Clock_tickReconfig()`** calls `Timer_setPeriodMicroseconds()` internally to reconfigure the timer. `Clock_tickReconfig()` fails if the timer cannot support `Clock.tickPeriod` at the current CPU frequency.
- ❑ **`Clock_tickStart()`** restarts the timer used to generate the Clock tick by calling `Timer_start()`.

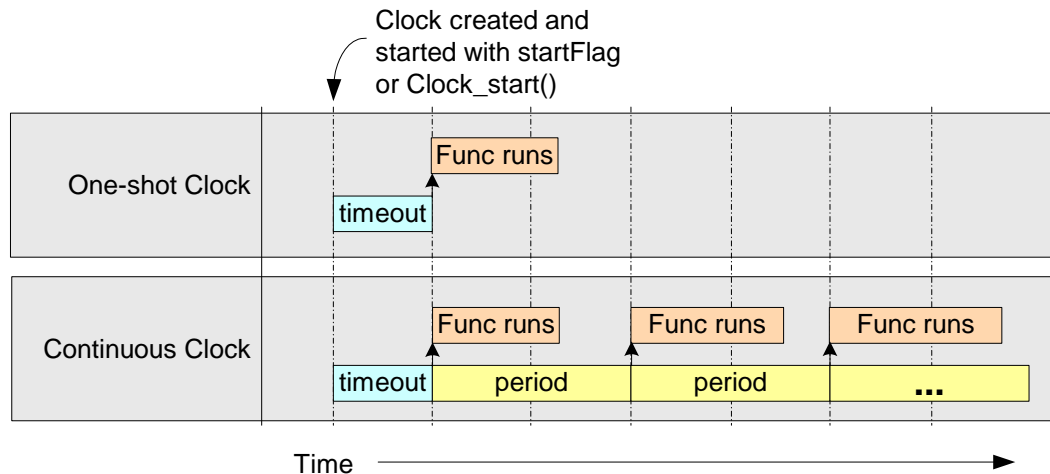

The Clock module lets you create Clock object instances, which reference functions that run when a timeout value specified in Clock ticks expires.

All Clock functions run in the context of a Swi. That is, the Clock module automatically creates a Swi for its use and run the Clock functions within that Swi. The priority of the Swi used by Clock can be changed by configuring `Clock.swiPriority`.

You can dynamically create clock instances using `Clock_create()`. Clock instances can be "one-shot" or continuous. You can start a clock instance when it is created or start it later by calling `Clock_start()`. This is controlled by the `startFlag` configuration parameter.

A function and a non-zero timeout value are required arguments to `Clock_create()`. The function is called when the timeout expires. The timeout value is used to compute the first expiration time. For one-shot Clock instances, the timeout value used to compute the single expiration time, and the period is zero. For periodic Clock instances, the timeout value is used to compute the first expiration time; the period value (part of the params) is used after the first expiration.

Table 4–1 *Timeline for One-shot and Continuous Clocks*

Clock instances (both one-shot and periodic) can be stopped and restarted by calling `Clock_start()` and `Clock_stop()`. Notice that while `Clock_tickStop()` stops the timer used to generate the Clock tick, `Clock_stop()` stops only one instance of a clock object. The expiration value is recomputed when you call `Clock_start()`.

APIs that start or stop a Clock Instance—`Clock_create()`, `Clock_start()`, and `Clock_stop()`—can only be called in the Swi context.

The Clock module provides the `Clock_setPeriod()`, `Clock_setTimeout()`, and `Clock_setFunc()` APIs to modify Clock instance properties for Clock instances that have been stopped.

Runtime example: This C example shows how to create a Clock instance. This instance is dynamic (runs repeatedly) and starts automatically. It runs the myHandler function every 5 ticks. A user argument (UArg) is passed to the function.

```
Clock_Params clockParams;
Error_Block eb;

Clock_Params_init(&clockParams);
clockParams.period = 5;
clockParams.startFlag = TRUE;
clockParams.arg = (UArg)0x5555;
obj1 = Clock_create(myHandler1, 5, &clockParams, &eb);
```

Configuration example: This example uses XDCtools to create a Clock instance with the same properties as the previous example.

```
var Clock = xdc.useModule('ti.sysbios.knl.Clock');

var clockParams = new Clock.Params();
clockParams.period = 5;
clockParams.startFlag = true;
clockParams.arg = (UArg)0x5555;
Program.global.clockInst1 = Clock.create("&myHandler1", 5,
    clockParams);
```

Runtime example: This C example uses some of the Clock APIs to print messages about how long a Task sleeps.

```
UInt32 time1, time2;
. . .

System_printf("task going to sleep for 10 ticks... \n");
time1 = Clock_getTicks();
Task_sleep(10);

time2 = Clock_getTicks();
System_printf("...awake! Delta time is: %lu\n",
    (ULong) (time2 - time1));
```

Runtime example: This C example uses some of the Clock APIs to lower the Clock module frequency.

```
BIOS_getCpuFreq(&cpuFreq);
cpuFreq.lo = cpuFreq.lo / 2;
BIOS_setCpuFreq(&cpuFreq);

key = Hwi_disable();
Clock_tickStop();
Clock_tickReconfig();
Clock_tickStart();
Hwi_restore(key);
```

4.3 Timer Module

The `ti.sysbios.hal.Timer` module presents a standard interface for using the timer peripherals. This module is described in detail in Section 6.3 because it is part of the Hardware Abstraction Layer (HAL) package

You can use this module to create a timer (that is, to mark a timer for use) and configure it to call a `tickFxn` when the timer expires. Use this module only if you do not need to do any custom configuration of the timer peripheral.

The timer can be configured as a one-shot or a continuous mode timer. The period can be specified in timer counts or microseconds.

4.4 Timestamp Module

The `xdc.runtime.Timestamp` module, as the name suggests, provides timestamping services. The Timestamp module can be used for benchmarking code and adding timestamps to logs. (In previous versions of DSP/BIOS, this is the functionality provided by `CLK_gethetime()`.)

Since `xdc.runtime.Timestamp` is provided by XDCtools, it is documented in the online help and the RTSC-pedia wiki.

Memory

This chapter describes issues related to memory use in SYS/BIOS.

Topic	Page
5.1 Background	5-2
5.2 Memory Map	5-4
5.3 Placing Sections into Memory Segments	5-11
5.4 Memory Map and Section Placement for MSP430	5-14
5.5 Stacks	5-14
5.6 Cache Configuration	5-17
5.7 Dynamic Memory Allocation	5-18
5.8 Heap Implementations	5-22

5.1 Background

This chapter deals with the configuration of static memory (memory mapping and section placement), caches, and stacks. It also provides information on dynamic memory allocation (allocating and freeing memory at run-time).

Static memory configuration relates to the "memory map" available to the executable and the placement of code and data into the memory map. The memory map is made up of internal memory regions that exist within the CPU and external memory regions located on the hardware board. See Section 5.2 for details about the memory map.

Code and data are placed in memory regions by the linker using the linker command file. The linker command file specifies a memory map. For each memory region, the linker command file specifies the origin or base address, length and attributes (read, write, and execute). A memory region specified in the linker command file is also called a "memory segment".

The following is a memory map specification from a linker command file:

```
MEMORY {
    IRAM (RWX) : org = 0x800000, len = 0x200000
    DDR : org = 0x80000000, len = 0x10000000
}
```

The linker command file also contains information on "memory section" placement, as shown in the following example. Sections are relocatable blocks of code produced by the compiler. The compiler produces some well-known sections for placements of various types of code and data, for example: `.text`, `.switch`, `.bss`, `.far`, `.cinit`, and `.const`. For details, see the appropriate compiler user's guide.

```
SECTIONS {
    .text: load >> DDR
    .switch: load >> DDR
    .stack: load > DDR
    .vecs: load >> DDR
    .args: load > DDR
    .systemem: load > DDR
    .far: load >> DDR
    .data: load >> DDR
    .cinit: load > DDR
    .bss: load > DDR
    .const: load > DDR
    .pinit: load > DDR
    .cio: load >> DDR
}
```

The linker places "memory sections" (such as .text and .cinit) into "memory segments" (such as IRAM) as specified by SECTIONS portion of the linker command file. See Section 5.3 for details about section placement.

Section 5.2 discusses the Memory Map for SYS/BIOS applications. (MSP430 users should see Section 5.4 instead.)

Section 5.3 discusses section placement in a SYS/BIOS application. (MSP430 users should see Section 5.4 instead.)

Section 5.5 discusses stacks, including how to configure the system stack and task stacks.

Section 5.6 covers cache configuration specific to the C6000 and cache runtime APIs.

Section 5.7 also discusses dynamic memory allocation. Runtime code can allocate and free memory from a "heap," which is a memory pool that has been set aside and managed for the purpose of dynamic memory allocation.

Various heap implementations are described in Section 5.8.

5.2 Memory Map

Note: If you are using the MSP430, see Section 5.4 instead. This section does not apply to the MSP430.

The memory map for an executable is determined by the device (which has internal memory) and the hardware board (which has external memory).

When you create a CCS v4.x project for an application that uses XDCtools and SYS/BIOS, you select a "RTSC platform". The memory map for on-device and external memory is determined by the RTSC platform. The RTSC platform also sets the clock speed and specifies memory section placement.

You select a RTSC platform when you create a new project or change the CCS build settings, not when you create a RTSC configuration.

Executables that need different memory maps must use different RTSC platforms even if they run on the same type of board.

The RTSC platform is tied to a particular device (CPU) and gets the internal memory map from the device—for example, IRAM and FLASH. The RTSC platform also contains the external memory specifications and cache settings. The internal and external memory segments together form the memory map.

5.2.1 Choosing an Available RTSC Platform

Before building a SYS/BIOS 6.x executable, you need to select the hardware board you will be using. You do this by selecting a RTSC platform either when you create a CCS project or in the **RTSC** tab of the project's **CCS Build** properties. The **RTSC Platform** field provides a drop-down list of all available RTSC platforms that match your **RTSC Target**; these items represent various evaluation boards available for your chosen device (CPU).

RTSC Target:	<input type="text" value="ti.targets.C64P"/>
RTSC Platform:	<input type="text" value="ti.platforms.evmDM6467"/> ▼
RTSC Build-Profile:	<input type="text" value="whole_program"/> ▼

To view the memory map for your platform, you can open the RTSC platform wizard by choosing **Tools > RTSC Tools > Platform > Edit/View**. Select the packages repository in your XDCtools installation. For example, C:\Program Files\Texas Instruments\xdctools_3_20\packages. Then, choose the RTSC platform package you are using and click **Next**.

In most cases, you begin application development using one of the evaluation boards, and can select one of the standard platforms from the drop-down list. You should select one of existing platforms if *all* of the following are true:

- You are in the development phase and are using an evaluation board.
- You do not care about cache sizes and are satisfied with the defaults set by the existing RTSC platform.
- You do not want to change the default section placement.
- You want the same clock rate as the evaluation board.

If any of these statements do not apply, see Section 5.2.2.

5.2.2 Creating a Custom RTSC Platform

At some point in the application development process, most customers build their own boards, choosing a TI device and adding custom external memory.

You will also need to create your own RTSC platform if any of the following items are true:

- You want to customize cache sizes.
- You want to manually override the default section placement.

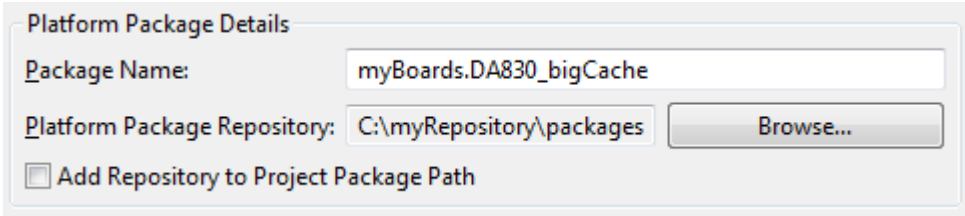

For such custom boards you will need to create a RTSC platform using the RTSC platform wizard. The platform wizard is a GUI tool that allows you to easily create a RTSC platform. Creating a custom RTSC platform gives you a lot of flexibility in terms of defining the memory map and selecting default memory segments for section placement.

To run the RTSC platform wizard, follow these steps:

- 1) In CCS v4.x, choose **Tools > RTSC Tools > Platform > New** from the menus. This opens the New Platform wizard.
- 2) Type a name for the package. This will be the name of the directory created to contain the RTSC platform package, and will be the name you select when you choose the RTSC platform for the project to use.

You can use a simple name or a period-delimited name. Periods correspond to directory levels when a platform package is created. For example, `myBoards.DA830_bigCache` will be created in `C:\myRepository\packages\myBoards\DA830_bigCache` if you are using `C:\myRepository\packages` as the repository location.

- 3) Next to the Platform Package Repository field, click **Browse**. Choose the location of the repository where you want to save your RTSC platform package. The default is `C:\Users\<username>\myRepository\packages`.

Platform Package Details

Package Name:

Platform Package Repository:

Add Repository to Project Package Path

If you haven't created a RTSC package repository before, and you don't want to use the default, create a new directory to contain the repository. In the directory you choose, create a sub-directory called "packages". For example, you might use `C:\myRepository\packages` as the repository. The full path to the repository should not contain any spaces.

- 4) Optionally, if you have already created a CCS project that you want to be able to use this RTSC platform, check the **Add Repository to Project Package Path** box. Then select the project that should have access to this repository. You don't need to do this now; you can also add repositories to projects from the project's Build Properties dialog.
- 5) Choose the **Device Family** and **Device Name** from the drop-down lists. For example:

Device Details

Device Family

Device Name

- 6) Click **Next**. You see the Device Page of the RTSC platform wizard.

Note: If you want another project to be able to use this RTSC platform, you can later add the repository that contains the RTSC platform to a project's properties by right-clicking on the project and choosing **Build Properties**. Choose the **CCS Build** category and then the **RTSC** tab. Click **Add** and browse the file-system for the repository you want the project to be able to search for RTSC platforms.

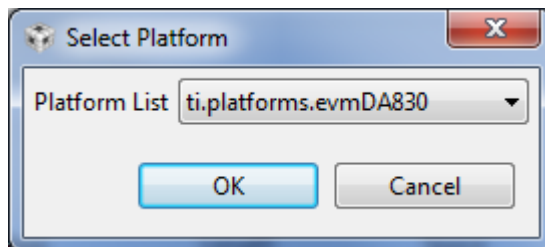

See the subsections that follow for ways to specify the cache, segment, and section use for your RTSC platform. You can also visit http://rtsc.eclipse.org/docs-tip/Demo_of_the_RTSC_Platform_Wizard_in_CCSv4 to watch demonstrations that use the RTSC platform wizard.

5.2.2.1 Getting and Setting the Clock Speed and Default Memory Settings

The Device Page opens with no clock speed setting, no external memory segments, and no memory section assignments. Generally, the first thing you will want to do is to import the default settings from an existing RTSC platform so that you can use those as a base for making the modifications you need.

To import defaults, follow these steps:

- 1) Click the **Import** button next to the Clock Speed field.
- 2) In the Select Platform dialog, choose the RTSC platform whose defaults you want to import, and click **OK**.

- 3) Click **Yes** in the confirmation dialog that asks if you are sure you want to change the settings.
- 4) You see the default clock speed and external memory settings. You can change these if you like.

Device Details

Device Name:
Device Family:
Clock Speed (MHz): Import...

Device Memory

Name	Base	Length	Space	Access
IRAM	0x11800000	0x00040000	code/data	RWX
L3_CBA_RAM	0x80000000	0x00020000	code/data	RWX
IROM	0x11700000	0x00100000	code/data	RX
L1PSRAM	0x11e00000	0x00008000	code	RWX

L1D Cache: L1P Cache: L2 Cache:

 Customize Memory

External Memory

SDRAM	0xC3000000	0x01000000	code/data	RWX

Memory Sections

Code Memory: Data Memory: Stack Memory:

5.2.2.2 Determining Cache Sizes for Custom RTSC Platforms

Since cache sizes affect the memory map, if you are using a C6000 target, you need to decide on the sizes you want to use when creating a RTSC platform. For example, if you are using the "ti.platforms.evmDA830" platform, the L1P, L1D, and L2 cache sizes affect the size of available L1PSRAM, L1DSRAM, and IRAM.

Since cache sizes are set in the RTSC platform, executables that need different cache configurations will also need different RTSC platforms.

The following example steps use the Device Page of the RTSC platform wizard to specify the maximum cache sizes for TMS320DA830 platform:

- 1) Set the L1D Cache to 32K. Set the L1P Cache to 32K. Set the L2 Cache to 256K.
- 2) Notice that the sizes of L1PSRAM, L1DSRAM and IRAM are adjusted down to zero.

Name	Base	Length	Space	Access
IRAM	0x11800000	0x00000000	code/data	RWX
L3_CBA_RAM	0x80000000	0x00020000	code/data	RWX
IROM	0x11700000	0x00100000	code/data	RX
L1PSRAM	0x11e00000	0x00000000	code	RWX
L1DSRAM	0x11f00000	0x00000000	data	RW

L1D Cache: 32k L1P Cache: 32k L2 Cache: 256k

Customize Memory

See Section 5.6 for more about cache configuration.

5.2.2.3 Selecting Default Memory Segments for Data, Code and Stack

The RTSC platform also determines the default memory segment for placement of code, data and stack. If you do not explicitly place a section, then the defaults are used. For example, if you do not configure the location of a Task stack in the .cfg file, then the task stack will be placed in the stack memory segment specified by the RTSC platform.

You can make coarse decisions on where you want your code, data, and stack to be placed by selecting values for data memory, code memory, and stack memory in your RTSC platform definition.

For example on the evmDA830, you may want your code in SDRAM and data in RAM. You can achieve this by selecting Code memory to be SDRAM and Data memory to be IRAM in the RTSC platform wizard.

Memory Sections

Code Memory: SDRAM Data Memory: IRAM Stack Memory: IRAM

See Section 5.3 for details about how you can use the RTSC configuration files to be more specific about how memory sections should be placed in memory segments.

5.2.2.4 Setting Custom Base Addresses and Lengths for Segments

You can customize the names, locations, sizes, type, and access for both internal and external memory segments.

To customize internal memory segments, begin by checking the **Customize Memory** box in the Device Memory area. You can then click on fields in the list of memory segments and make changes. In the **Name**, **Base**, and **Length** columns, type the value you want to use. In the **Space** and **Access** columns, you can select from a list of options.

Device Memory

Name	Base	Length	Space	Access
IRAM	0x11800000	0x00040000	code/data	RWX
L3_CBA_RAM	0x80000000	0x00020000	code/data	RWX
IROM	0x11700000	0x00100000	code/data	RX
L1PSRAM	0x11e00000	0x00008000	code/data	RWX

L1D Cache: 0k L1P Cache: 0k

Customize Memory

To customize external memory segments, you can right-click in the External Memory area and choose **Insert Row** or **Delete Row**.

External Memory

Name	Base	Length	Space	Access
SDRAM	0xC3000000	0x01000000	code/data	RWX

Insert Row
Delete Row

In the new row, type a **Name**, **Base** address, and **Length** for the memory segment. Choose the type of memory **Space** and the permitted **Access** to this memory.

To watch a demo that shows how to customize memory segments, see http://rtsc.eclipse.org/docs-tip/Demo_of_Customizing_Memory_Sections.

5.3 Placing Sections into Memory Segments

Note: If you are using the MSP430, see Section 5.4 instead. This section does not apply to the MSP430.

Once you have specified the RTSC platform for your application to define the memory map it will use, you can place sections into memory segments as part of the RTSC configuration in the project's .cfg file.

The memory segments that are available are determined by the RTSC platform, along with the default section placement in memory segments. See Section 5.2. for details

Note: To place sections into segments in the .cfg file, you will need to edit the source of your .cfg script in a text editor. Currently, you *cannot* use the XGCONF GUI editor.

5.3.1 Configuring Simple Section Placement

In a RTSC configuration file, section placement is done through the `Program.sectMap[]` array.

The simplest way to configure the segment in which a section should be placed is as follows:

```
Program.sectMap[".foo"] = IRAM;
```

This example would cause the IRAM segment to be used both for loading and running the .foo section.

5.3.2 Configuring Section Placement Using a SectionSpec

The `Program.sectMap[]` array maps section names to structures of the type `SectionSpec`. If you use the simple statement syntax shown in the previous section, you don't need to create a `SectionSpec` structure. Using a `SectionSpec` structure gives you more precise control over how the run and load memory segments (or addresses) for a section are specified.

The `SectionSpec` structure contains the following fields.

- runSegment.** The segment where the section is to be run.
- loadSegment.** The segment where the section is to be loaded.
- runAddress.** Starting address where the section is to be run. You cannot specify both the `runSegment` and `runAddress`.

- ❑ **loadAddress.** Starting address where the section is to be loaded. You cannot specify both the loadSegment and the loadAddress.
- ❑ **runAlign.** Alignment of the section specified by runSegment. If you specify the runSegment, you can also specify runAlign.
- ❑ **loadAlign.** Alignment of the section specified by loadSegment. If you specify the loadSegment, you can also specify loadAlign.
- ❑ **type.** You can use this field to define various target-specific flags to identify the section type. For example, COPY, DSECT, and NOLOAD.
- ❑ **fill.** If specified, this value is used to initialize an uninitialized section.

The following .cfg file statements specify the memory segments where the .foo section is to be loaded and run.

```
Program.sectMap[".foo"] = new Program.SectionSpec();
Program.sectMap[".foo"].loadSegment = "FLASH";
Program.sectMap[".foo"].runSegment = "RAM";
```

If you specify only the loadSegment or runSegment for a section, the default behavior is to use the specified segment for both loading and running.

The following statements place the Swi_post() function into the IRAM memory segment:

```
Program.sectMap[".text:_ti_sysbios_knl_Swi_post__F"]
    = new Program.SectionSpec();
Program.sectMap[".text:_ti_sysbios_knl_Swi_post__F"] = "IRAM";
```

The following statements place all static instances for the Task module into the .taskStatic section:

```
Var Task = xdc.useModule('ti.sysbios.knl.Task');

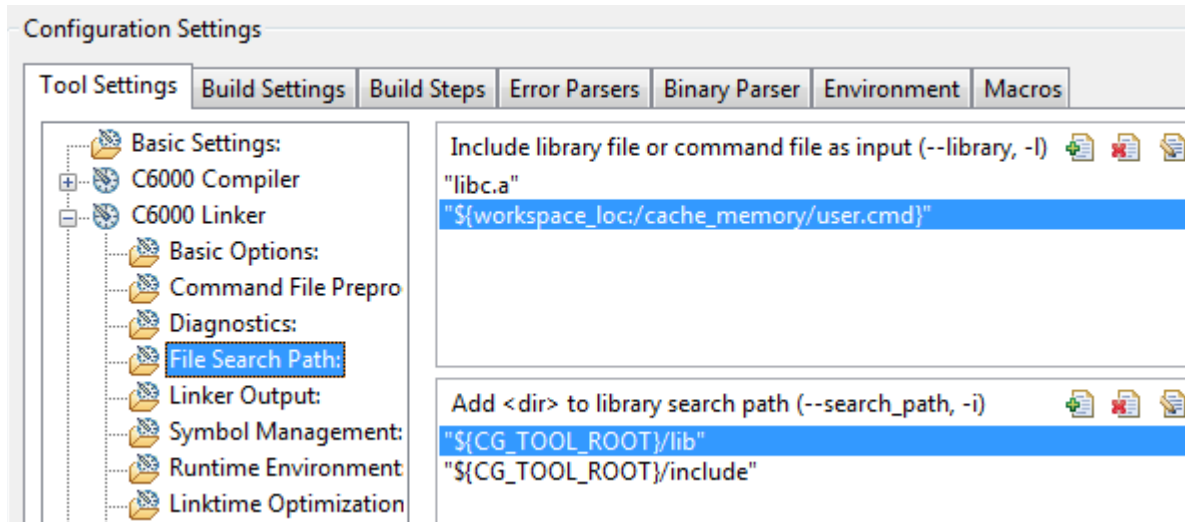

Task.common$.instanceSection = ".taskStatic";
Program.sectMap[".taskStatic"] = new Program.SectionSpec();
Program.sectMap[".taskStatic"].loadSegment = "IRAM";
```

Configuration statements that specify sections using the sectMap array affect the section placement in the linker command file that is generated from the configuration.

5.3.3 Using a Custom linker.cmd File for Other Section Properties

If you need to use other linker command file options to place sections such as GROUP and UNION (or other advanced options not supported by the SectionSpec structure), you will need to add your own custom linker command file to the CCS project.

For example, the following figure shows a linker command file called `user.cmd` that will be included in the build. In this example, the file is in the `cache_memory` directory of the CCS workspace.

Your linker command file should not specify a `MEMORY` table or any sections that are already placed by the `.cmd` file that is generated from the `.cfg` configuration file. For example, your custom linker command file should not place compiler sections such as `.text` and `.bss`.

To add your own linker command file, follow these steps:

- 1) Right-click on the project in CCS and select **Build Properties** from the pop-up menu.
- 2) Select the **C/C++ Build** category.
- 3) In the **Tool Settings** tab, scroll down to the **Cxxx Linker** list and choose the **File Search Path** category.
- 4) Click the "+" icon in the **Include library file or command file as input** area.
- 5) Type or browse for the path to your linker command file. Then click **OK**.
- 6) Click **OK** in the Properties dialog to apply your changes.

5.4 Memory Map and Section Placement for MSP430

When you create a project for the MSP430 in CCSv4.2, you must select an MSP430 device as part of the project settings (for example, MSP430F5435A) in the CCS project creation wizard. A linker command file specific to the selected device is automatically added to the project by CCSv4.2.

In the RTSC Configuration Settings page of the wizard, a RTSC target and a RTSC platform are automatically selected based on your previous selections. Select "whole_program" as the RTSC profile to get optimized code that will fit easily on MSP430 devices.

The RTSC platform for the MSP430 differs from other RTSC platforms in that it does not define the memory map for the device. Instead, the linker command file added by the project wizard is used directly. Any changes to the memory map and section placement can be made by editing the linker command file directly. See the *MSP430 Optimizing C/C++ Compiler User's Guide* for more details on linker command file options.

Note that an additional RTSC-generated linker command file is added to the project; this file places a few sections that are SYS/BIOS specific. This command file assumes that "FLASH" and "RAM" are part of the memory map.

5.5 Stacks

SYS/BIOS uses a single system stack for hardware interrupts and a separate task stack for each Task instance.

5.5.1 System Stack

You can configure the size of the System stack, which is used as the stack for hardware interrupts and software interrupts (and by the Idle functions if Task is disabled). You should set the System stack size to meet the application's needs. See Section 2.4.3 for information about system stack size requirements.

You can use the .stack section to control the location of the system stack. For example, the following configuration statements place the system stack of size 0x400 in the IRAM segment.

```
Program.stack = 0x400;  
Program.sectMap[".stack"] = "IRAM";
```

Setting `Program.stack` generates appropriate linker options in the linker command file to allow the system stack to be allocated at link time. For example, the linker command file for a C6000 application might include the command option `-stack 0x0400`.

See your project's auto-generated linker command file for symbols related to the system stack size and location. For C6000 these include `__TI_STACK_END` and `__STACK_SIZE`.

5.5.2 Task Stacks

If the Task module is enabled, SYS/BIOS creates an additional stack for each Task instance the application contains (plus one task stack for the Idle threads). See Section 2.5.3 for information about task stack size requirements.

You can specify the size of a Task's stack in the configuration file. (You can use XGCONF to do this or edit the `.cfg` file directly.) For example:

```
var Task = xdc.useModule('ti.sysbios.knl.Task');

/* Set default stack size for tasks */
Task.defaultStackSize = 1024;

/* Set size of idle task stack */
Task.idleTaskStackSize = 1024;

/* Create a Task Instance and set stack size */
var tskParams = new Task.Params;
tskParams.stackSize = 1024;
var task0 = Task.create('&task0Fxn', tskParams);
```

You can control the location of task stacks for statically-created Tasks by using `Program.sectMap[]`. For example:

```
/* Place idle task stack section */
Program.sectMap[".idleTaskStackSection"] = "IRAM";

/* Place other static task stacks */
Program.sectMap[".taskStackSection"] = "IRAM";
```

5.5.3 ROV for System Stacks and Task Stacks

At run-time, the ROV tool in CCS provides a detailed view for each of the Task instances. For information about ROV, see the RTSC-pedia page at http://rtsc.eclipse.org/docs-tip/RTSC_Object_Viewer. The Detailed tab shows the task stack information and status.

The screenshot shows the ROV tool interface. On the left, a tree view displays the project structure: static.out > ti > sysbios > knl > Task. The main pane is divided into four tabs: Basic, Detailed, Module, and Raw. The 'Detailed' tab is active, showing a table with the following data:

label	stackPeak	stackSize	stackBase
	68	1024	0xc30124e8
	68	2048	0xc30128e8
ti.sysbios.knl.Task.IdleTask	68	1024	0xc30130e8

The Module tab of the Task view shows the HwiStack (which is the system stack) information and status.

The screenshot shows the ROV tool interface with the 'Module' tab selected. The tree view on the left is the same as in the previous screenshot. The main pane shows a table with the following data:

address	hwiStackPeak	hwiStackSize	hwiStackBase
0xc3010328	388	4096	0xc30134e8

5.6 Cache Configuration

C6000 cache sizes in SYS/BIOS 6.x are determined by the RTSC platform you choose. To change cache sizes, create or modify the RTSC platform using the platform wizard as described in Section 5.2.2.2.

The following subsections describe ways you can use the family-specific Cache modules in SYS/BIOS to manipulate caching behavior.

5.6.1 Configure Cache Size Registers at Startup

For C6000 targets, the `ti.sysbios.hal.Cache` module gets cache sizes from the RTSC platform and sets the cache size registers at startup time. The `ti.sysbios.hal.Cache` module is a generic module whose implementations are provided in the family-specific `ti.sysbios.family.*.Cache` modules. See Section 6.4 for more about the Cache module and its implementations.

For example on the DA830, the Cache module sets the L1PCFG, L1DCFG and L2CFG registers at startup time.

5.6.2 Configure Parameters to Set MAR Registers

For C6000 targets, the `ti.sysbios.family.c64p.Cache` module defines `Cache.MAR###-###` configuration parameters that allow you to control which external memory addresses are cacheable or non-cacheable. For example, `Cache_MAR128_159` is one such configuration parameter. These configuration parameters directly map to the MAR registers on the device. Each external memory address space of 16 MB is controlled by one MAR bit (0: noncacheable, 1:cacheable).

The SYS/BIOS Cache module has module-wide configuration parameters that map to the MAR registers.

By default the C64P Cache module makes all memory regions defined in the platform cacheable by setting all of the corresponding MAR bits to 0x1. To disable caching on a DA830 device for the external memory range from 8000 0000h to 80FF FFFFh, you set `Cache.MAR128_159 = 0x0` as follows. This sets register MAR128 to 0.

```
var Cache = xdc.useModule('ti.sysbios.family.c64p.Cache');
Cache.MAR_128_159 = 0x0;
```

After the MAR bit is set for an external memory space, new addresses accessed by the CPU will be cached in L2 cache or, if L2 is disabled, in L1. See device-specific reference guides for MAR registers and their mapping to external memory addresses.

At system startup, the Cache module writes to the MAR registers and configures them.

5.6.3 Cache Runtime APIs

For any target that has a cache, the `ti.sysbios.hal.Cache` module provides APIs to manipulate caches at runtime. These include the `Cache_enable()`, `Cache_disable()`, `Cache_wb()`, and `Cache_inv()` functions. See Section 6.4.1 for details.

5.7 Dynamic Memory Allocation

A "Heap" is a module that implements the `IHeap` interface. Heaps are dynamic memory managers: they manage a specific piece of memory and support allocating and freeing pieces ("blocks") of that memory.

Memory allocation sizes are measured in "Minimum Addressable Units" (MAUs) of memory. An MAU is the smallest unit of data storage that can be read or written by the CPU. For the C28x, this is an 16-bit word. For the all other currently supported target families—including C6000, ARM, and MSP430—this is an 8-bit byte.

5.7.1 Memory Policy

You can reduce the amount of code space used by an application by setting the `memoryPolicy` on a global or per-module basis. This is particularly useful on targets where the code memory is significantly constrained.

The options are:

- ❑ **DELETE_POLICY.** This is the default. The application creates and deletes objects (or objects for this module) at runtime. You need both the `MODULE_create()` functions and the `MODULE_delete()` functions to be available to the application.
- ❑ **CREATE_POLICY.** The application creates objects (or objects for this module) at runtime. It does not delete objects at runtime. You need the `MODULE_create()` functions to be available to the application, but not the `MODULE_delete()` functions.
- ❑ **STATIC_POLICY.** The application creates all objects (or all objects for this module) in the configuration file. You don't need the `MODULE_create()` or the `MODULE_delete()` functions to be available to the application.

For example, the following configuration statements set the default memory policy for all modules to static instance creation only:

```
var Defaults = xdc.useModule('xdc.runtime.Defaults');
var Types = xdc.useModule('xdc.runtime.Types');

Defaults.memoryPolicy = Types.STATIC_POLICY;
```

5.7.2 Specifying the Default System Heap

By default, the system heap used by SYS/BIOS is a HeapStd heap with size = 0x1000. For many applications, this is too small. If your application will allocate memory dynamically, you should configure a heap suitable for your application.

You can define and resize a system heap in your configuration by creating a heap and assigning that heap to the Memory.defaultHeapInstance property as follows:

```
var HeapMem = xdc.useModule('ti.sysbios.heaps.HeapMem');

/* Create default heap and hook it into Memory */
var heapMemParams = new HeapMem.Params();

heapMemParams.size = 0x2000;
var heapMem = HeapMem.create(heapMemParams);

Memory.defaultHeapInstance = heapMem;
```

See the SYS/BIOS templates for additional configuration examples that configure a system heap.

5.7.3 Using the xdc.runtime.Memory Module

All dynamic allocation is done through the xdc.runtime.Memory module. The Memory module provides APIs such as Memory_alloc() and Memory_free(). All Memory APIs take an IHeap_Handle as their first argument. The Memory module does very little work itself; it makes calls to the Heap module through the IHeap_Handle. The Heap module is responsible for managing the memory. Using Memory APIs makes applications and middleware portable and not tied to a particular heap implementation.

IHeap_Handles to be used with Memory APIs are obtained by creating Heap instances statically or dynamically. When The IHeap_Handle passed to the Memory APIs is NULL, the default system heap is used. See Section 5.7.2.

Configuration example: This example configures a default system heap using the HeapMem implementation. It makes that the default heap. It also creates a heap using the HeapBuf implementation for use by task0.

```
var Memory = xdc.useModule('xdc.runtime.Memory');
var HeapMem = xdc.useModule('ti.sysbios.heaps.HeapMem');
var HeapBuf = xdc.useModule('ti.sysbios.heaps.HeapBuf');

/* Create a default system heap using ti.bios.HeapMem. */
var heapMemParams = new HeapMem.Params;
heapMemParams.size = 2048;
heapMemParams.sectionName = "systemHeap";
Program.global.systemHeap = HeapMem.create(heapMemParams);
Program.sectMap["systemHeap"] = "DDR";

/* Plug in systemheap as default heap to be used by Memory */
Memory.defaultHeapInstance = Program.global.heap0;

/* Create a heap using HeapBuf */
var heapBufParams = new HeapBuf.Params;
heapBufParams.blockSize = 128;
heapBufParams.numBlocks = 2;
heapBufParams.align = 8;
heapBufParams.sectionName = "otherHeap";
Program.global.otherHeap = HeapBuf.create(heapBufParams);
Program.sectMap["otherHeap"] = "DDR";
```

Runtime example: This example allocates and frees memory from both heaps configured in the previous example. It allocates from the system heap by passing NULL to Memory_alloc as the IHeap_Handle. It allocates from the "otherheap" by getting and passing the IHeap_Handle for that heap.

```
#include <xdc/std.h>
#include <xdc/runtime/IHeap.h>
#include <xdc/runtime/System.h>
#include <xdc/runtime/Memory.h>

extern IHeap_Handle systemHeap, otherHeap;

Void main()
{
    Ptr buf1, buf2;

    /* Alloc and free using systemHeap */
    buf1 = Memory_alloc(NULL, 128, 0, NULL);
    Memory_free(NULL, buf1, 128);

    /* Alloc and free using otherHeap */
    buf2 = Memory_alloc(otherHeap, 128, 0, NULL);
    Memory_free(otherHeap, buf2, 128);
}
```

5.7.4 Specifying a Heap for Module Dynamic Instances

You can specify the default heap to be used when allocating memory for dynamically-created module instances. The configuration property that controls the default heap for all modules is Default.common\$.instanceHeap.

For example, these configuration statements specify the heap for allocating instances:

```
var HeapMem = xdc.useModule('ti.sysbios.heaps.HeapMem');

var heapMemParams = new HeapMem.Params;
heapMemParams.size = 8192;
var heap1 = HeapMem.create(heapMemParams);
Default.common$.instanceHeap = heap1;

heapMemParams.size = 4096;
var heap2 = HeapMem.create(heapMemParams);
```

If you do not specify a separate heap for instances, the heap specified for Memory.defaultHeapInstance will be used (see Section 5.7.2).

5.7.5 Using malloc() and free()

In addition to allocating from Heaps created with SYS/BIOS modules, your application can use the standard runtime library malloc() and free() functions. These allocate and deallocate memory from a separate heap.

You can use the Program.heap parameter to specify the size (in characters) of the heap managed by the malloc() function. For example:

```
Program.heap = 4096;
```

The XDCtools xdc.runtime.HeapStd heap implementation uses malloc() and free().

5.8 Heap Implementations

The xdc.runtime.Memory module is the common interface for all memory operations. The actual memory management is performed by a Heap instance, such as an instance of HeapMem or HeapBuf. For example, Memory_alloc() is used at runtime to dynamically allocate memory. All of the Memory APIs take a Heap instance as one of their parameters. Internally, the Memory module calls into the heap's interface functions.

The xdc.runtime.Memory module is documented in the XDCtools online help and the RTSC-pedia wiki. Implementations of Heaps provided by SYS/BIOS are discussed here.

XDCtools provides the HeapMin and HeapStd heap implementations. See the CDOC help for XDCtools for details on these implementations.

SYS/BIOS provides the following Heap implementations:

- ❑ **HeapMem.** Allocate variable-size blocks. Section 5.8.1
- ❑ **HeapBuf.** Allocate fixed-size blocks. Section 5.8.2
- ❑ **HeapMultiBuf.** Specify variable-size allocation, but internally allocate from a variety of fixed-size blocks. Section 5.8.3

This table compares SYS/BIOS heap implementations:

Table 5–1 Heap Implementation Comparison

Module	Description/Characteristics	Limitations
ti.sysbios.heaps.HeapMem	Uses Gate to protect during allocation and freeing, accepts any block size	Slower, non-deterministic

Module	Description/Characteristics	Limitations
ti.sysbios.heaps.HeapBuf	Fast, deterministic, non-blocking	Allocates blocks of a single size
ti.sysbios.heaps.HeapMultiBuf	Fast, deterministic, non-blocking, multiple-block sizes supported	Limited number of block sizes

Different heap implementations optimize for different memory management traits. The HeapMem module (Section 5.8.1) accepts requests for all possible sizes of blocks, so it minimizes internal fragmentation. The HeapBuf module (Section 5.8.2), on the other hand, can only allocate blocks of a fixed size, so it minimizes external fragmentation in the heap and is also faster at allocating and freeing memory.

The Inter-Processor Communication (IPC) product provides several heap implementations intended for use in multi-processor applications.

5.8.1 HeapMem

HeapMem can be considered the most "flexible" of the Heaps because it allows you to allocate variable-sized blocks. When the size of memory requests is not known until runtime, it is ideal to be able to allocate exactly how much memory is required each time. For example, if a program needs to store an array of objects, and the number of objects needed isn't known until the program actually executes, the array will likely need to be allocated from a HeapMem.

The flexibility offered by HeapMem has a number of performance tradeoffs.

- ❑ **External Fragmentation.** Allocating variable-sized blocks can result in fragmentation. As memory blocks are "freed" back to the HeapMem, the available memory in the HeapMem becomes scattered throughout the heap. The total amount of free space in the HeapMem may be large, but because it is not contiguous, only blocks as large as the "fragments" in the heap can be allocated.

This type of fragmentation is referred to as "external" fragmentation because the blocks themselves are allocated exactly to size, so the fragmentation is in the overall heap and is "external" to the blocks themselves.

- ❑ **Non-Deterministic Performance.** As the memory managed by the HeapMem becomes fragmented, the available chunks of memory are stored on a linked list. To allocate another block of memory, this list must be traversed to find a suitable block. Because this list can vary in length, it's not known how long an allocation request will take, and so the performance becomes "non-deterministic".

A number of suggestions can aid in the optimal use of a HeapMem.

- ❑ **Larger Blocks First.** If possible, allocate larger blocks first. Previous allocations of small memory blocks can reduce the size of the blocks available for larger memory allocations.
- ❑ **Overestimate Heap Size.** To account for the negative effects of fragmentation, use a HeapMem that is significantly larger than the absolute amount of memory the program will likely need.

When a block is freed back to the HeapMem, HeapMem combines the block with adjacent free blocks to make the available block sizes as large as possible.

Note: HeapMem uses a user-provided lock to lock access to the memory. For details, see Section 3.3, *Gates*.

The following examples create a HeapMem instance with a size of 1024 MAUs.

Configuration example: The first example uses XDCtools to statically configure the heap:

```
var HeapMem = xdc.useModule('ti.sysbios.heaps.HeapMem');

/* Create heap as global variable so it can be used in C code */
Program.global.myHeap = HeapMem.create();
Program.global.myHeap.size = 1024;
```

Runtime example: This second example uses C code to dynamically create a HeapMem instance:

```
HeapMem_Params prms;
static char *buf[1024];
HeapMem_Handle heap;

HeapMem_Params_init(&prms);
prms.size = 1024;
prms.buf = (Ptr)buf;
heap = HeapMem_create(&prms, NULL);
```

HeapMem uses a Gate (see the Gates section for an explanation of Gates) to prevent concurrent accesses to the code which operates on a HeapMem's list of free blocks. The type of Gate used by HeapMem is statically configurable through the HeapMem's common defaults.

Configuration example: This example configures HeapMem to use a GateMutexPri to protect critical regions of code.

```
var GateMutexPri = xdc.useModule('ti.sysbios.gates.GateMutexPri');  
var HeapMem = xdc.useModule('ti.sysbios.heaps.HeapMem');
```

```
HeapMem.common$.gate = GateMutexPri.create();
```

The type of Gate used depends upon the level of protection needed for the application. If there is no risk of concurrent accesses to the heap, then "null" can be assigned to forgo the use of any Gate, which would improve performance. For an application that could have concurrent accesses, a GateMutex is a likely choice. Or, if it is possible that a critical thread will require the HeapMem at the same time as a low-priority thread, then a GateMutexPri would be best suited to ensuring that the critical thread receives access to the HeapMem as quickly as possible. See Section 3.3.2.2, *GateMutexPri* for more information.

5.8.2 HeapBuf

HeapBuf is used for allocating fixed-size blocks of memory, and is designed to be fast and deterministic. Often a program needs to create and delete a varying number of instances of a fixed-size object. A HeapBuf is ideal for allocating space for such objects, since it can handle the request quickly and without any fragmentation.

A HeapBuf may also be used for allocating objects of varying sizes when response time is more important than efficient memory usage. In this case, a HeapBuf will suffer from "internal" fragmentation. There will never be any fragmented space in the heap overall, but the allocated blocks themselves may contain wasted space, so the fragmentation is "internal" to the allocated block.

Allocating from and freeing to a HeapBuf always takes the same amount of time, so a HeapBuf is a "deterministic" memory manager.

The following examples create a HeapBuf instance with 10 memory blocks of size 128.

Configuration example: The first example uses XDCtools to statically configure the heap. In this configuration example, no `bufSize` or `bufSize` parameter needs to be specified, since the configuration can compute these values and allocate the correct sections at link time.

```
var HeapBuf = xdc.useModule('ti.sysbios.heaps.HeapBuf');

/* Create heap as global variable so it can be used in C code */
Program.global.myHeap = HeapBuf.create();
Program.global.myHeap.blockSize = 128;
Program.global.myHeap.numBlocks = 10;
```

Runtime example: This second example uses C code to dynamically create a `HeapBuf` instance. In this example, you must pass the `bufSize` and `buf` parameters. Be careful when specifying these runtime parameters. The `blockSize` needs to be a multiple of the worst-case structure alignment size. And `bufSize` should be equal to `blockSize * numBlocks`. The worst-case structure alignment is target dependent. On C6x and ARM devices, this value is 8. The base address of the buffer should also be aligned to this same size.

```
HeapBuf_Params prms;
static char *buf[1280];
HeapBuf_Handle heap;

HeapBuf_Params_init(&prms);
prms.blockSize = 128;
prms.numBlocks = 10;
prms.buf = buf;
prms.bufSize = 1280;
heap = HeapBuf_create(&prms, NULL);
```

5.8.3 HeapMultiBuf

`HeapMultiBuf` is intended to balance the strengths of `HeapMem` and `HeapBuf`. Internally, a `HeapMultiBuf` maintains a collection of `HeapBuf` instances, each with a different block size, alignment, and number of blocks. A `HeapMultiBuf` instance can accept memory requests of any size, and simply determines which of the `HeapBufs` to allocate from.

A `HeapMultiBuf` provides more flexibility in block size than a single `HeapBuf`, but largely retains the fast performance of a `HeapBuf`. A `HeapMultiBuf` instance has the added overhead of looping through the `HeapBufs` to determine which to allocate from. In practice, though, the number of different block sizes is usually small and is always a fixed number, so a `HeapMultiBuf` can be considered deterministic by some definitions.

A HeapMultiBuf services a request for any memory size, but always returns one of the fixed-sized blocks. The allocation will not return any information about the actual size of the allocated block. When freeing a block back to a HeapMultiBuf, the size parameter is ignored. HeapMultiBuf determines the buffer to free the block to by comparing addresses.

When a HeapMultiBuf runs out of blocks in one of its buffers, it can be configured to allocate blocks from the next largest buffer. This is referred to as "block borrowing". See the online reference described in Section 1.6.1 for more about HeapMultiBuf.

The following examples create a HeapMultiBuf that manages 1024 MAUs of memory, which are divided into 3 buffers. It will manage 8 blocks of size 16 MAUs, 8 blocks of size 32 MAUs, and 5 blocks of size 128 MAUs as shown in the following diagram.

Program.global.myHeap

16 MAUs	16 MAUs	16 MAUs	16 MAUs	16 MAUs	16 MAUs	16 MAUs	16 MAUs
32 MAUs		32 MAUs		32 MAUs		32 MAUs	
32 MAUs		32 MAUs		32 MAUs		32 MAUs	
				128 MAUs			
				128 MAUs			
				128 MAUs			
				128 MAUs			
				128 MAUs			

Configuration example: The first example uses XDCtools to statically configure the HeapMultiBuf instance:

```
var HeapMultiBuf = xdc.useModule('ti.sysbios.heaps.HeapMultiBuf');

/* HeapMultiBuf without blockBorrowing. */
/* Create as a global variable to access it from C Code. */
Program.global.myHeap = HeapMultiBuf.create();

Program.global.myHeap.numBufs = 3;
Program.global.myHeap.blockBorrow = false;
Program.global.myHeap.bufParams =
    [{blockSize: 16, numBlocks:8, align: 0},
     {blockSize: 32, numBlocks:8, align: 0},
     {blockSize: 128, numBlocks:5, align: 0}];
```

Runtime example: This second example uses C code to dynamically create a HeapMultiBuf instance:

```
HeapMultiBuf_Params prms;
HeapMultiBuf_Handle heap;

/* Create the buffers to manage */
Char buf0[128];
Char buf1[256];
Char buf2[640];

/* Create the array of HeapBuf_Params */
HeapBuf_Params bufParams[3];

/* Load the default values */
HeapMultiBuf_Params_init(&prms);
prms.numBufs = 3;
prms.bufParams = bufParams;

HeapBuf_Params_init(&prms.bufParams[0]);
prms.bufParams[0].align = 0;
prms.bufParams[0].blockSize = 16;
prms.bufParams[0].numBlocks = 8;
prms.bufParams[0].buf = (Ptr) buf0;
prms.bufParams[0].bufSize = 128;

HeapBuf_Params_init(&prms.bufParams[1]);
prms.bufParams[1].align = 0;
prms.bufParams[1].blockSize = 32;
prms.bufParams[1].numBlocks = 8;
prms.bufParams[1].buf = (Ptr) buf1;
prms.bufParams[1].bufSize = 256;

HeapBuf_Params_init(&prms.bufParams[2]);
prms.bufParams[2].align = 0;
prms.bufParams[2].blockSize = 128;
prms.bufParams[2].numBlocks = 5;
prms.bufParams[2].buf = (Ptr) buf2;
prms.bufParams[2].bufSize = 640;

heap = HeapMultiBuf_create(&prms, NULL);
```

Hardware Abstraction Layer

This chapter describes modules that provide hardware abstractions.

Topic	Page
6.1 Hardware Abstraction Layer APIs	6-2
6.2 HWI Module	6-3
6.3 Timer Module	6-11
6.4 Cache Module	6-16
6.5 HAL Package Organization	6-18

6.1 Hardware Abstraction Layer APIs

SYS/BIOS provides services for configuration and management of interrupts, cache, and timers. Unlike other SYS/BIOS services such as threading, these modules directly program aspects of a device's hardware and are grouped together in the Hardware Abstraction Layer (HAL) package. Services such as enabling and disabling interrupts, plugging of interrupt vectors, multiplexing of multiple interrupts to a single vector, and cache invalidation or writeback are described in this chapter.

Note: Any configuration or manipulation of interrupts and their associated vectors, the cache, and timers in a SYS/BIOS application must be done through the SYS/BIOS HAL APIs. In earlier versions of DSP/BIOS, some HAL services were not available and developers were expected to use functions from the Chip Support Library (CSL) for a device. The most recent releases of CSL (3.0 or above) are designed for use in applications that do not use SYS/BIOS. Some of their services are not compatible with SYS/BIOS. Usage of CSL interrupt, cache, and timer functions and SYS/BIOS in the same application should be avoided since this combination is known to result in complex interrupt-related debugging problems.

The HAL APIs fall into two categories:

- ❑ Generic APIs that are available across all targets and devices
- ❑ Target/device-specific APIs that are available only for a specific device or ISA family

The generic APIs are designed to cover the great majority of use cases. Developers who are concerned with ensuring easy portability between different TI devices are best served by using the generic APIs as much as possible. In cases where the generic APIs cannot enable use of a device-specific hardware feature that is advantageous to the software application, you may choose to use the target/device-specific APIs, which provide full hardware entitlement.

In this chapter, an overview of the functionality of each HAL package is provided along with usage examples for that package's generic API functions. After the description of the generic functions, examples of target/device-specific APIs, based on those provided for 'C64x+ devices, are also given. For a full description of the target/device-specific APIs available for a particular family or device, please refer to the API reference documentation. section 6.5, *HAL Package Organization* provides an overview of the generic HAL packages and their associated target/device-specific packages to facilitate finding the appropriate packages.

6.2 HWI Module

The ti.sysbios.hal.Hwi module provides a collection of APIs for managing hardware interrupts. These APIs are generic across all supported targets and devices and should provide sufficient functionality for most applications.

6.2.1 Associating a C Function with a System Interrupt Source

To associate a user-provided C function with a particular system interrupt, you create a Hwi object that encapsulates information regarding the interrupt required by the Hwi module.

The standard static and dynamic forms of the "create" function are supported by the ti.sysbios.hal.Hwi module.

Configuration example: The following example statically creates a Hwi object that associates interrupt 5 with the "myIsr" C function using default instance configuration parameters:

```
Var Hwi = xdc.useModule('ti.sysbios.hal.Hwi');

Hwi.create(5, '&myIsr');
```

Runtime example: The C code required to configure the same interrupt dynamically would be as follows:

```
#include <ti/sysbios/hal/Hwi>

Hwi_create(5, myIsr, NULL, NULL);
```

The NULL, NULL arguments are used when the default instance parameters and generic error handling is satisfactory for creating a Hwi object.

6.2.2 Hwi Instance Configuration Parameters

The following configuration parameters and their default values are defined for each Hwi object. For a more detailed discussion of these parameters and their values see the ti.sysbios.hal.Hwi module in the online documentation. (For information on running online help, see Section 1.6.1, *Using the API Reference Help System*, page 1-10.)

- The "maskSetting" defines how interrupt nesting is managed by the interrupt dispatcher.

```
MaskingOption maskSetting = MaskingOption_SELF;
```

- ❑ The configured "arg" parameter will be passed to the Hwi function when the dispatcher invokes it.

```
UArg arg = 0;
```

- ❑ The "enableInt" parameter is used to automatically enable or disable an interrupt upon Hwi object creation.

```
Bool enableInt = true;
```

- ❑ The "eventId" accommodates 'C6000 devices that allow dynamic association of a peripheral event to an interrupt number. The default value of -1 leaves the eventId associated with an interrupt number in its normal (reset) state (that is, no re-association is required).

```
Int eventId = -1;
```

- ❑ The "priority" parameter is provided for those architectures that support interrupt priority setting. The default value of -1 informs the Hwi module to set the interrupt priority to a default value appropriate to the device.

```
Int priority = -1;
```

6.2.3 Creating a Hwi Object Using Non-Default Instance Configuration Parameters

Building on the examples given in Section 6.2.1, the following examples show how to associate interrupt number 5 with the "myIsr" C function, passing "10" as the argument to "myIsr" and leaving the interrupt disabled after creation.

Configuration example:

```
var Hwi = xdc.useModule('ti.sysbios.hal.Hwi');

/* initialize hwiParams to default values */
var hwiParams = new Hwi.Params;

hwiParams.arg = 10;           /* Set myIsr5 argument to 10 */
hwiParams.enableInt = false; /* override default setting */

/* Create a Hwi object for interrupt number 5
 * that invokes myIsr5() with argument 10 */
Hwi.create(5, '&myIsr', hwiParams);
```

Runtime example:

```
#include <ti/sysbios/hal/Hwi>

Hwi_Params hwiParams;

/* initialize hwiParams to default values */
Hwi_Params_init(&hwiParams);

hwiParams.arg = 10;
hwiParams.enableInt = FALSE;

Hwi_create(5, myIsr, &hwiParams, NULL);
```

6.2.4 Enabling and Disabling Interrupts

You can enable and disable interrupts globally as well as individually with the following Hwi module APIs:

- ❑ `UInt Hwi_enable();`
Globally enables all interrupts. Returns the previous enabled/disabled state.
- ❑ `UInt Hwi_disable();`
Globally disables all interrupts. Returns the previous enabled/disabled state.
- ❑ `Hwi_restore(UInt key);`
Restores global interrupts to their previous enabled/disabled state. The "key" is the value returned from `Hwi_disable()` or `Hwi_enable()`.
- ❑ The APIs that follow are used for enabling, disabling, and restoring specific interrupts given by "intNum". They have the same semantics as the global `Hwi_enable/disable/restore` APIs.:
 - `UInt Hwi_enableInterrupt(UInt intNum);`
 - `UInt Hwi_disableInterrupt(UInt intNum);`
 - `Hwi_restoreInterrupt(UInt key);`
- ❑ `Hwi_clearInterrupt(UInt intNum);`
Clears "intNum" from the set of currently pending interrupts.

Disabling hardware interrupts is useful during a critical section of processing.

On the C6000 platform, `Hwi_disable()` clears the GIE bit in the control status register (CSR). On the C2000 platform, `Hwi_disable()` sets the INTM bit in the ST1 register.

6.2.5 A Simple Example Hwi Application

The following example creates two Hwi objects. One for interrupt number 5 and another for interrupt number 6. For illustrative purposes, one interrupt is created statically and the other dynamically. An idle function that waits for the interrupts to complete is also added to the Idle function list.

Configuration example:

```
/* Pull in BIOS module required by ALL BIOS applications */
xdc.useModule('ti.sysbios.BIOS');

/* Pull in XDC runtime System module for various APIs used */
xdc.useModule('xdc.runtime.System');

/* Get handle to Hwi module for static configuration */
var Hwi = xdc.useModule('ti.sysbios.hal.Hwi');

/* Initialize hwiParams to default values */
var hwiParams = new Hwi.Params;

/* Set myIsr5 argument */
hwiParams.arg = 10;

/* Keep interrupt 5 disabled until later */
hwiParams.enableInt = false;

/* Create a Hwi object for interrupt number 5
 * that invokes myIsr5() with argument 10 */
Hwi.create(5, '&myIsr5', hwiParams);

/* Add an idle thread 'myIdleFunc' that monitors interrupts. */
var Idle = xdc.useModule(ti.sysbios.knl.Idle);

Idle.addFunc('&myIdleFunc');
```

Runtime example:

```
#include <xdc/std.h>
#include <xdc/runtime/System.h>
#include <ti/sysbios/hal/Hwi>

Bool Hwi5 = FALSE;
Bool Hwi6 = FALSE;
```

```
Main(Void)  {
    Hwi_Params hwiParams;

    /* Initialize hwiParams to default values */
    Hwi_Params_init(&hwiParams);

    /* Set myIsr6 parameters */
    hwiParams.arg = 12;
    hwiParams.enableInt = FALSE;

    /* Create a Hwi object for interrupt number 6
     * that invokes myIsr6() with argument 12 */
    Hwi_create(6, myIsr6, &hwiParams, NULL);

    /* enable both interrupts */
    Hwi_enableInterrupt(5);
    Hwi_enableInterrupt(6);

    /* start BIOS */
    BIOS_start();
}

/* Runs when interrupt 5 occurs */
Void myIsr5(UArg arg)  {
    If (arg == 10) {
        Hwi5 = TRUE;
    }
}

/* Runs when interrupt 6 occurs */
Void myIsr6(UArg arg)  {
    If (arg == 12) {
        Hwi6 = TRUE;
    }
}

/* The Idle thread checks for completion of interrupts 5 & 6
 * and exits when they have both completed. */
Void myIdleFunc()
{
    If (Hwi5 && Hwi6) {
        System_printf("Both interrupts have occurred!");
        System_exit(0);
    }
}
```

6.2.6 The Interrupt Dispatcher

To consolidate code that performs register saving and restoration for each interrupt, SYS/BIOS provides an interrupt dispatcher that automatically performs these actions for an interrupt routine. Use of the Hwi dispatcher allows ISR functions to be written in C.

In addition to preserving the interrupted thread's context, the SYS/BIOS Hwi dispatcher orchestrates the following actions:

- ❑ Disables SYS/BIOS Swi and Task scheduling during interrupt processing
- ❑ Automatically manages nested interrupts on a per-interrupt basis.
- ❑ Invokes any configured "begin" Hwi Hook functions.
- ❑ Runs the Hwi function.
- ❑ Invokes any configured "end" Hwi Hook functions.
- ❑ Invokes Swi and Task schedulers after interrupt processing to perform any Swi and Task operations resulting from actions within the Hwi function.

Note: The *interrupt* keyword or INTERRUPT pragma must not be used to define the C function invoked by the Hwi dispatcher. The Hwi dispatcher contains this functionality, and the use of the C modifier will cause catastrophic results.

Functions that use the *interrupt* keyword or INTERRUPT pragma may not use the Hwi dispatcher and may not call SYS/BIOS APIs.

6.2.7 Registers Saved and Restored by the Interrupt Dispatcher

The registers saved and restored by the dispatcher in preparation for invoking the user's Hwi function conform to the "saved by caller" or "scratch" registers as defined in the register usage conventions section of the C compiler documents. For more information, either about which registers are saved and restored, or about the TMS320 functions conforming to the Texas Instruments C runtime model, see the *Optimizing Compiler User's Guide* for your platform.

6.2.8 Additional Target/Device-Specific Hwi Module Functionality

As described in Section 6.5, the `ti.sysbios.hal.Hwi` module is implemented using the RTSC proxy-delegate mechanism. All `ti.sysbios.hal.Hwi` module APIs are forwarded to a target/device-specific Hwi module that implements all of the `ti.sysbios.hal.Hwi` required APIs. Each of these Hwi module implementations provide additional APIs and functionality unique to the family/device and can be used instead of the `ti.sysbios.hal.Hwi` module if needed.

For example, the 'C64x+ target-specific Hwi module, `ti.sysbios.family.c64p.Hwi`, provides the following APIs in addition to those defined in the `ti.sysbios.hal.Hwi` module:

- `Hwi_eventMap(UInt intNum, UInt eventId);`
Remaps a peripheral event number to an interrupt number.

- `Bits16 Hwi_enableIER(Bits16 mask);`
`Bits16 Hwi_disableIER(Bits16 mask);`
`Bits16 Hwi_restoreIER(Bits16 mask);`

These three APIs allow enabling, disabling and restoring a set of interrupts defined by a "mask" argument. These APIs provide direct manipulation of the 'C64x+'s internal IER registers.

To gain access to these additional APIs, you use the target/device-specific Hwi module associated with the 'C64x+ target rather than the `ti.sysbios.hal.Hwi` module.

For documentation on the target/device-specific Hwi modules, see the CDOC documentation for `ti.sysbios.family.*.Hwi`. For example, `ti.sysbios.family.c28.Hwi`.

The following examples are modified versions of portions of the example in Section 6.2.5. The modifications are shown in **bold**.

Configuration example:

```
var Hwi = xdc.useModule('ti.sysbios.family.c64p.Hwi');

/* Initialize hwiParams to default values */
var hwiParams = new Hwi.Params;

/* Set myIsr5 parameters */
hwiParams.arg = 10;
hwiParams.enableInt = false;

/* Create a Hwi object for interrupt number 5
 * that invokes myIsr5() with argument 10 */
Hwi.create(5, '&myIsr5', hwiParams);
```

Runtime example:

```
#include <ti/sysbios/family/c64p/Hwi>

Main(Void) {
    Hwi_Params hwiParams;

    /* Initialize hwiParams to default values */
    Hwi_Params_init(&hwiParams);

    /* Set myIsr6 parameters */
    hwiParams.arg = 12;
    hwiParams.enableInt = FALSE;

    /* Create a Hwi object for interrupt number 6
     * that invokes myIsr6() with argument 12 */
    Hwi_create(6, myIsr6, &hwiParams, NULL);

    /* Enable interrupts 5 & 6 simultaneously using the C64x+
     * Hwi module Hwi_enableIER() API. */
    Hwi_enableIER(0x0060);

    . . .
```

6.3 Timer Module

The `ti.sysbios.hal.Timer` module presents a standard interface for using the timer peripherals. It hides any target/device-specific characteristics of the timer peripherals. It inherits the `ti.sysbios.interfaces.ITimer` interface.

You can use this module to create a timer (that is, to mark a timer for use) and configure it to call a `tickFxn` when the timer expires. Use this module only if you do not need to do any custom configuration of the timer peripheral.

This module has a configuration parameter called `TimerProxy` which is plugged by default with a target/device-specific implementation. For example, the implementation for C64x targets is `ti.sysbios.family.c64.Timer`.

The timer can be configured as a one-shot or a continuous mode timer. The period can be specified in timer counts or microseconds.

The timer interrupt always uses the Hwi dispatcher. The `Timer tickFxn` runs in the context of a Hwi thread. The `Timer` module automatically creates a Hwi instance for the timer interrupt.

The `Timer_create()` API takes a `timerId`. The `timerId` can range from zero to a target/device-specific value determined by the `TimerProxy`. The `timerId` is just a logical ID; its relationship to the actual timer peripheral is controlled by the `TimerProxy`.

If it does not matter to your program which timer is used, in a C program or XDCtools configuration you can specify a `timerId` of `Timer_ANY_TIMER` which means "use any available timer". For example, in an XDCtools configuration use:

```
Timer.create(Timer_ANY_TIMER, "&myIsr", timerParams);
```

In a C program, use:

```
Timer_create(Timer_ANY_TIMER, myIsr, &timerParams, NULL);
```

The `timerParams` includes a number of parameters to configure the timer. For example `timerParams.startMode` can be set to `StartMode_AUTO` or `StartMode_USER`. The `StartMode_AUTO` setting indicates that statically-created timers will be started in `BIOS_start()` and dynamically-created timers will be started at `create()` time. The `StartMode_USER` indicates that your program starts the timer using `Timer_start()`. See the example in Section 6.3.1.

You can get the total number of timer peripherals by calling `Timer_getNumTimers()` at runtime. This includes both used and available timer peripherals. You can query the status of the timers by calling `Timer_getStatus()`.

If you want to use a specific timer peripheral or want to use a custom timer configuration (setting timer output pins, emulation behavior, etc.), you should use the target/device-specific Timer module. For example, `ti.sysbios.family.c64.Timer`.

The Timer module also allows you to specify the `extFreq` (external frequency) property for the timer peripheral and provides an API to get the timer frequency at runtime. This external frequency property is supported only on targets where the timer frequency can be set separately from the CPU frequency.

You can use `Timer_getFreq()` to convert from timer interrupts to real time.

The Timer module provides APIs to start, stop, and modify the timer period at runtime. These APIs have the following side effects.

- ❑ `Timer_setPeriod()` stops the timer before setting the period register. It then restarts the timer.
- ❑ `Timer_stop()` stops the timer and disables the timer interrupt.
- ❑ `Timer_start()` clears counters, clears any pending interrupts, and enables the timer interrupt before starting the timer.

Runtime example: This C example creates a timer with a period of 10 microseconds. It passes an argument of 1 to the `myIsr` function. It instructs the Timer module to use any available timer peripheral:

```
Timer_Params timerParams;  
Timer_Params_init(&timerParams);  
timerParams.period = 10;  
timerParams.periodType = Timer_PeriodType_MICROSECS;  
timerParams.arg = 1;  
Timer_create(Timer_ANY_TIMER, myIsr, &timerParams, NULL);
```

Configuration example: This XDCtools example statically creates a timer with the same characteristics as the previous C example. It specifies a `timerId` of 1:

```
var timer = xdc.useModule('ti.sysbios.hal.Timer');  
var timerParams = new Timer.Params();  
timerParams.period = 10;  
timerParams.periodType = Timer.PeriodType_MICROSECS;  
timerParams.arg = 1;  
timer.create(1, '&myIsr', timerParams);
```

Runtime example: This C example specifies a frequency for a timer that it creates. The `extFreq.hi` and `extFreq.lo` properties set the high and low 32-bit portions of the structure used to represent the frequency in Hz.

```
Timer_Params timerParams;

Timer_Params_init(&timerParams);
timerParams.extFreq.lo = 270000000; /* 27 MHz */
timerParams.extFreq.hi = 0;

...
Timer_create(Timer_ANY_TIMER, myIsr, &timerParams, NULL);
```

Configuration example: This XDCtools configuration example specifies a frequency for a timer that it creates.

```
var Timer = xdc.useModule('ti.sysbios.hal.Timer');
var timerParams = new Timer.Params();
timerParams.extFreq.lo = 270000000;
timerParams.extFreq.hi = 0;
...
Timer.create(1, '&myIsr', timerParams);
```

Runtime example: This C example creates a timer that runs the `tickFxn()` every 2 milliseconds using any available timer peripheral. It also creates a task that, when certain conditions occur, changes the timer's period from 2 to 4 milliseconds. The `tickFxn()` itself prints a message that shows the current period of the timer.

```
Timer_Handle timerHandle;

Int main(Void)
{
    Error_Block eb;
    Timer_Params timerParams;

    Timer_Params_init(&timerParams);
    timerParams.period = 2000; /* 2 ms */
    timerHandle = Timer_create(Timer_ANY_TIMER, tickFxn,
                              &timerParams, &eb);

    if (Error_check(&eb)) {
        System_abort("Timer create failed");
    }

    Task_create(masterTask, NULL, NULL);
}
```

```
Void masterTask(UArg arg0 UArg arg1)
{
    ...
    // Condition detected requiring a change to timer period
    Timer_stop(timerHandle);
    Timer_setPeriodMicroSecs(4000); /* change 2ms to 4ms */
    Timer_start(timerHandle());
    ...
}

Void tickFxn(UArg arg0 UArg arg1)
{
    System_printf("Current period = %d\n",
        Timer_getPeriod(timerHandle));
}
```

6.3.1 Target/Device-Specific Timer Modules

As described in Section 6.5, the `ti.sysbios.hal.Timer` module is implemented using the RTSC proxy-delegate mechanism. A separate target/device-specific Timer module is provided for each supported family. For example, the `ti.sysbios.timers.timer64.Timer` module acts as the timer peripherals manager for the 64P family.

These target/device-specific modules provide additional configuration parameters and APIs that are not supported by the generic `ti.sysbios.hal.Timer` module.

In the case of the `ti.sysbios.timers.timer64.Timer` module, the configuration parameters `controllnit`, `globalControllnit`, and `emuMgtInnit` are provided to configure various timer properties. This module also exposes a `Hwi Params` structure as part of its create parameters to allow you to configure the `Hwi` object associated with the Timer. This module also exposes a `Timer_reconfig()` API to allow you to reconfigure a statically-created timer.

Configuration example: This XDCtools configuration example specifies timer parameters, including target/device-specific parameters for a timer called `myTimer` that it creates.

```
var Timer = xdc.useModule('ti.sysbios.timers.timer64.Timer');

var timerParams = new Timer.Params();
timerParams.period = 2000;      //2ms
timerParams.arg = 1;
timerParams.startMode = Timer.StartMode_USER;
timerParams.controlInit.invout = 1;
timerParams.globalControlInit.chained = false;
timerParams.emuMgtInit.free = false;
timerParams.suspSrc = SuspSrc_ARM;

Program.global.myTimer = Timer.create(1, "&myIsr",
    timerParams);
```

Runtime example: This C example uses the `myTimer` created in the preceding XDCtools configuration example and reconfigures the timer with a different function argument and `startMode` in the program's `main()` function before calling `BIOS_start()`.

```
#include <ti/sysbios/timers/timer64/Timer.h>
#include <xdc/cfg/global.h>

Void myIsr(UArg arg)
{
    System_printf("myIsr arg = %d\n", (Int)arg);
    System_exit(0);
}

Int main(Int argc, char* argv[])
{
    Timer_Params timerParams;

    Timer_Params_init(&timerParams);
    timerParams.arg = 2;
    timerParams.startMode = Timer_StartMode_AUTO;
    Timer_reconfig(myTimer, &timerParams, NULL);

    BIOS_start();

    return(0);
}
```

6.4 Cache Module

The cache support provides API functions that perform cache coherency operations at the cache line level or globally. The cache coherency operations are:

- ❑ **Invalidate.** Makes valid cache lines invalid and discards the content of the affected cache lines.
- ❑ **Writeback.** Writes the contents of cache lines to a lower-level memory, such as the L2 cache or external memory, without discarding the lines in the original cache.
- ❑ **Writeback-Invalidation.** Writes the contents of cache lines to lower-level memory, and then discards the contents of the lines in the original cache.

6.4.1 Cache Interface Functions

The cache interface is defined in `ti.sysbios.interfaces.ICache`. The Cache interface contains the following functions. The implementations for these functions are target/device-specific.

- ❑ **Cache_enable();** Enables all caches.
- ❑ **Cache_disable();** Disables all caches.
- ❑ **Cache_inv(blockPtr, byteCnt, wait);** Invalidates the specified range of memory. When you invalidate a cache line, its contents are discarded and the cache tags the line as "dirty" so that next time that particular address is read, it is obtained from external memory. All lines in the range are invalidated in all caches.
- ❑ **Cache_wb(blockPtr, byteCnt, wait);** Writes back the specified range of memory. When you perform a writeback, the contents of the cache lines are written to lower-level memory. All lines within the range are left valid in caches and the data within the range is written back to the source memory.
- ❑ **Cache_wbInv(blockPtr, byteCnt, wait);** Writes back and invalidates the specified range of memory. When you perform a writeback, the contents of the cache lines are written to lower-level memory. When you invalidate a cache line, its contents are discarded. All lines within the range are written back to the source memory and then invalidated in all caches.

These Cache APIs operate on an address range beginning with the starting address of `blockPtr` and extending for the specified byte count. The range of addresses operated on is quantized to whole cache lines in each cache.

The `blockPtr` points to an address in non-cache memory that may be cached in one or more caches or not at all. If the `blockPtr` does not correspond to the start of a cache line, the start of that cache line is used.

If the `byteCnt` is not equal to a whole number of cache lines, the `byteCnt` is rounded up to the next size that equals a whole number of cache lines.

If the `wait` parameter is true, then this function waits until the invalidation operation is complete to return. If the `wait` parameter is false, this function returns immediately. You can use `Cache_wait()` later to ensure that this operation is complete.

- ❑ **Cache_wait();** Waits for the cache `wb/wbInv/inv` operation to complete. A cache operation is not truly complete until it has worked its way through all buffering and all memory writes have landed in the source memory.

As described in Section 6.5, this module is implemented using the RTSC proxy-delegate mechanism. A separate target/device-specific Cache module is provided for each supported family.

Additional APIs are added to this module for certain target/device-specific implementations. For example, the `ti.sysbios.family.c64p.Cache` module adds APIs specific to the C64x+ caches. These extensions have functions that also have the prefix "Cache_".

Currently the C64x+, C674x, and ARM caches are supported.

C64x+ specific: The caches on these devices are Level 1 Program (L1P), Level 1 Data (L1D), and Level 2 (L2). See the *TMS320C64x+ DS P Megamodule Reference Guide* (SPRU871) for information about the L1P, L1D, and L2 caches.

6.5 HAL Package Organization

The three SYS/BIOS modules that reside in the ti.sysbios.hal package: Hwi, Timer, and Cache require target/device-specific API implementations to achieve their functionality. In order to provide a common set of APIs for these modules across all supported families/devices, SYS/BIOS uses the RTSC proxy-delegate module mechanism. (See the "RTSC Interface Primer: Lesson 12" for details.)

Each of these three modules serves as a proxy for a corresponding target/device-specific module implementation. In use, all Timer/Hwi/Cache API invocations are forwarded to an appropriate target/device-specific module implementation.

During the configuration step of the application build process, the proxy modules in the ti.sysbios.hal package locate and bind themselves to appropriate delegate module implementations based on the current target and platform specified in the user's config.bld file. The delegate binding process is done internally.

The following tables show currently supported (as of this document's publication) Timer, Hwi, and Cache delegate modules that may be selected based on an application's target and device. The mapping of target/device to the delegate modules used by Timer, Cache, and Hwi is accessible through a link in the ti.sysbios.hal package online help.

Table 6–1 Proxy to Delegate Mappings

Proxy Module	Delegate Modules
ti.sysbios.hal.Timer	ti.sysbios.hal.TimerNull * ti.sysbios.timers.dmtimer.Timer ti.sysbios.timers.gptimer.Timer ti.sysbios.timers.timer64.Timer ti.sysbios.family.c28.Timer ti.sysbios.family.c67p.Timer ti.sysbios.family.msp430.Timer ti.sysbios.family.windows.Timer ti.sysbios.family.arm.<various>.Timer
ti.sysbios.hal.Hwi	ti.sysbios.family.c28.Hwi ti.sysbios.family.c64p.Hwi ti.sysbios.family.c67p.Hwi ti.sysbios.family.msp430.Hwi ti.sysbios.family.windows.Hwi ti.sysbios.family.arm.<various>.Hwi

Table 6–1 Proxy to Delegate Mappings

Proxy Module	Delegate Modules
ti.sysbios.hal.Cache	ti.sysbios.hal.CacheNull * ti.sysbios.family.c64p.Cache ti.sysbios.family.c67p.Cache ti.sysbios.family.arm.Cache

* For targets/devices for which a Timer or Cache module has not yet been developed, the hal.TimerNull or hal.CacheNull delegate is used. In TimerNull/CacheNull, the APIs defined in ITimer/ICache are implemented using null functions.

For the proxy-delegate mechanism to work properly, both the proxy and the delegate modules must be implementations of a common RTSC interface specification. The Timer, Hwi, and Cache interface specifications reside in ti.sysbios.interfaces and are ITimer, IHwi, and ICache respectively. These interface specifications define a minimum set of general APIs that, it is believed, will satisfy a vast majority of application requirements. For those applications that may need target/device-specific functionality not defined in these interface specifications, the corresponding Timer, Hwi, and Cache delegate modules contain extensions to the APIs defined in the interface specifications.

To access to these extended API sets, you must directly reference the target/device-specific module in your configuration file and include its corresponding header file in your C source files.

Instrumentation

This chapter describes modules and other tools that can be used for instrumentation purposes.

Topic	Page
7.1 Overview of Instrumentation	7-2
7.2 Load Module	7-2
7.3 Real-Time Analysis Tools in CCS v4.x	7-5
7.4 RTA Agent	7-16
7.5 Performance Optimization	7-20

7.1 Overview of Instrumentation

Much of the instrumentation available to SYS/BIOS applications is provided by the XDCtools modules and APIs. See the XDCtools documentation for details about the Assert, Diags, Error, Log, LoggerBuf, and LoggerSys modules.

7.2 Load Module

The `ti.sysbios.utils.Load` module reports execution times and load information for threads in a system.

SYS/BIOS manages four distinct levels of execution threads: hardware interrupt service routines, software interrupt routines, tasks, and background idle functions. The Load module reports execution time and load on a per-task basis, and also provides information globally for hardware interrupt service routines, software interrupt routines, and idle functions (in the form of the idle task). It can also report an estimate of the global CPU load, which is computed as the percentage of time in the measurement window that was *not* spent in the idle loop. More specifically, the load is computed as follows.

$$\text{global CPU load} = 100 * (1 - ((x * t) / w))$$

where:

- ❑ 'x' is the number of times the idle loop has been executed during the measurement window.
- ❑ 't' is the minimum time for a trip around the idle loop, meaning the time it takes to complete the idle loop if no work is being done in it.
- ❑ 'w' is the length in time of the measurement window.

Any work done in the idle loop is included in the CPU load. In other words, any time spent in the loop beyond the shortest trip around the idle loop is counted as non-idle time.

The Load module relies on "update" to be called to compute load and execution times from the time when "update" was last called. This is automatically done for every period specified by `Load.windowInMs` (default = 500 ms) in a `ti.sysbios.knl.Idle` function when `Load.updateInIdle` is set to true (the default). The benchmark time window is the length of time between 2 calls to "update".

The execution time is reported in units of `xdc.runtime.Timestamp` counts, and the load is reported in percentages.

By default, load data is gathered for all threads. You can use the configuration parameters `Load.hwiEnabled`, `Load.swiEnabled`, and `Load.taskEnabled` to select which type(s) of threads are monitored.

7.2.1 Load Module Configuration

The Load module has been setup to provide data with as little configuration as possible. Using the default configuration, load data is gathered and logged for all threads roughly every 500 ms.

The following code configures the Load module to write Load statistics to a LoggerBuf instance.

```
var LoggerBuf = xdc.useModule('xdc.runtime.LoggerBuf');
var Load = xdc.useModule('ti.sysbios.utils.Load');
var Diags = xdc.useModule('xdc.runtime.Diags');

var loggerBuf = LoggerBuf.create();
Load.common$.logger = loggerBuf;
Load.common$.diags_USER4 = Diags.ALWAYS_ON;
```

For information on advanced configuration and caveats of the Load module, see the online reference documentation.

7.2.2 Obtaining Load Statistics

Load statistics recorded by the Load module can be obtained in one of two ways:

- **Load module logger.** If you configure the Load module with a logger and have turned on the diags_USER4, the statistics gathered by the Load module are recorded to the load module's logger instance. You can use the RTA tool to visualize the Load based on these Log records. See Section 7.3 for more information.

Alternatively, you can configure the logger to print the logs to the console. The global CPU load log prints a percentage. For example:

```
LS_cpuLoad: 10
```

The global Swi and Hwi load logs print two numbers: the time in the thread, and the length of the measurement window. For example:

```
LS_hwiLoad: 13845300,158370213
LS_swiLoad: 11963546,158370213
```

These evaluate to loads of 8.7% and 7.6%.

The Task load log uses the same format, with the addition of the Task handle address as the first argument. For example:

```
LS_taskLoad: 0x11802830,56553702,158370213
```

This evaluates to a load of 35.7%.

- ❑ **Runtime APIs.** You can also choose to call `Load_getTaskLoad()`, `Load_getGlobalSwiLoad()`, `Load_getGlobalHwiLoad()` or `Load_getCPULoad()` at any time to obtain the statistics at runtime.

The `Load_getCPULoad()` API returns an actual percentage load, whereas `Load_getTaskLoad()`, `Load_getGlobalSwiLoad()`, and `Load_getGlobalHwiLoad()` return a `Load_Stat` structure. This structure contains two fields, the length of time in the thread, and the length of time in the measurement window. The load percentage can be calculated by dividing these two numbers and multiplying by 100%. However, the Load module also provides a convenience function, `Load_calculateLoad()`, for this purpose. For example, the following code retrieves the Hwi Load:

```
Load_Stat stat;
UInt32 hwiLoad;

Load_getGlobalHwiLoad(&stat);

hwiLoad = Load_calculateLoad(&stat);
```

7.3 Real-Time Analysis Tools in CCS v4.x

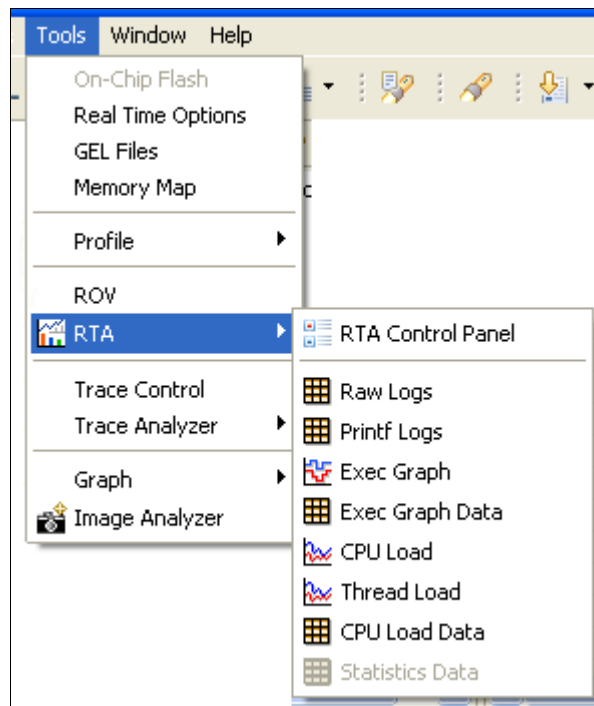

SYS/BIOS 6 supports a number of Real-Time Analysis (RTA) tools that are provided in Code Composer Studio v4.x. These tools provides raw log information as well as execution and load graphs in real-time (while the target is running) or stop mode (while the target is halted).

The subsections that follow briefly introduce the RTA tools.

In order to use RTA tools, your application must be configured to include support for RTA. SYS/BIOS 6 includes an RTA "Agent" module, `ti.sysbios.rta.Agent`, which retrieves Log data from the target and sends it to the host. See Section 7.4 for details on configuring RTA support.

You may open RTA tools in CCS at any time, typically just before running the target application or while the application is running.

To open the tool, choose **Tools > RTA** from the CCS menu bar. This shows a list of the available graphs and tables provided for real-time analysis.

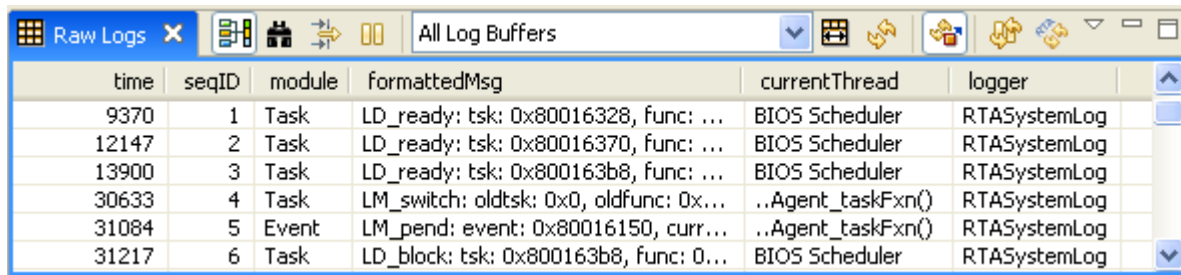

In addition to the RTA tools, the Runtime Object Viewer (ROV) is a stop-mode debugging tool provided by XDCtools. You can use ROV with SYS/BIOS applications to see state information about all the modules in your application. For information, see the RTSC-pedia page on ROV at http://rtsc.eclipse.org/docs-tip/RTSC_Object_Viewer.

7.3.1 Raw Logs

By default, the Raw Logs tool displays complete unformatted log data. The default columns displayed are: time, seqID, module, formattedMsg, currentThread, and logger.

You can open this tool by choosing **Tools > RTA > Raw Logs** from the CCS menu bar.

time	seqID	module	formattedMsg	currentThread	logger
9370	1	Task	LD_ready: tsk: 0x80016328, func: ...	BIOS Scheduler	RTASystemLog
12147	2	Task	LD_ready: tsk: 0x80016370, func: ...	BIOS Scheduler	RTASystemLog
13900	3	Task	LD_ready: tsk: 0x800163b8, func: ...	BIOS Scheduler	RTASystemLog
30633	4	Task	LM_switch: oldtsk: 0x0, oldfunc: 0x...	..Agent_taskFxn()	RTASystemLog
31084	5	Event	LM_pend: event: 0x80016150, curr...	..Agent_taskFxn()	RTASystemLog
31217	6	Task	LD_block: tsk: 0x800163b8, func: 0...	BIOS Scheduler	RTASystemLog

This table displays all the log records that have been sent from the target. This contains all the records used by the RTA tools to populate their graphs and tables. In addition, the following types of logs are also shown:

- Any Log records from other modules
- Any user-defined Logs or Log_print*() calls

This tool contains the following toolbar icons:

 Toggle **View With Group** setting on and off. (Shift+G)

 Open the **Find In** dialog for searching this log.

 **Filter** the log records to match a pattern by using the Set Filter Expression dialog.

 **Freeze Data Updates** from the target. This is useful when you are using the Find or Filter dialogs. (Shift+F5)

 Choose the type of log messages you want listed.

 **Auto Fit Columns** sets the column widths to fit their current contents.

 **Refresh** the GUI displays. This button does not collect data from the target.

 **Stream RTA Data** toggles the collection of RTA data at runtime. The default is on if the application is configured to use RTDX. Changing the setting of this toggle affects the setting in all RTA tools.

 **Toggle Autorefresh Mode** is available only when the target is stopped. Toggling this icon on causes the RTA tools to collect stop mode data from the target once per target halt. Changing the setting of this toggle affects the setting in all RTA tools. This mode is on by default.

 **Refresh RTA Buffers in Stop Mode** is available only when the target is stopped, and only when the Autorefresh Mode toggle is off. Clicking this icon causes the RTA tools to collect stop mode data from the target one time.

See Section 7.4.2 and Section 7.4.3 for more about using the , , and  icons.

"Groups" in the RTA views refers to synchronizing the views so that moving around in one view causes similar movement to happen automatically in another. For example, if you group the CPU load graph with Raw Logs, then if you click on the CPU Load graph, the Raw Log displays the closest record to where you clicked in the graph.

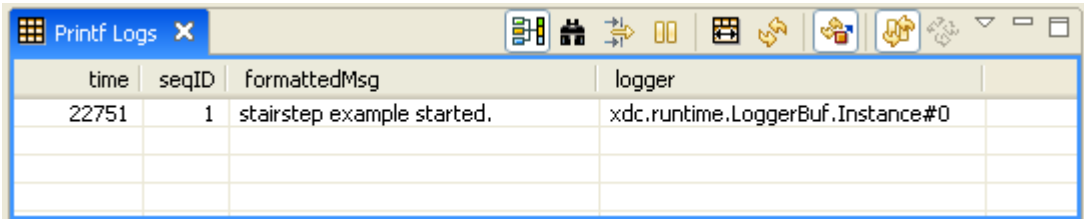

You can right-click on this tool to choose from a menu of options. In addition to some of the toolbar commands, you can use the following additional commands from the right-click menu:

- Column Settings.** This command opens a dialog that lets you hide or display various columns. You can also change the alignment, font, and display format of a column (for example, decimal, binary, or hex).
- Copy.** This command copies the selected text to the clipboard.
- Enable Auto Scroll.** This command allows the log to scroll automatically as new data is available.
- Data > Export Selected.** This command lets you select a .csv (comma-separated value) file to contain the selected data.
- Data > Export All.** This command lets you select a .csv (comma-separated value) file to contain all the data currently displayed in the log.
- Groups.** This command lets you define groups to contain various types of log messages.

7.3.2 Printf Logs

The Printf Log is a convenient way to view all the user-generated trace and printf logs. By default, the Printf Log tool displays the time, seqID, formattedMsg, and logger.

You can open this tool by choosing **Tools > RTA > Printf Logs** from the CCS menu bar.

time	seqID	formattedMsg	logger
22751	1	stairstep example started.	xdc.runtime.LoggerBuf.Instance#0

The toolbar icons and right-click menu for the Printf Logs tool are the same as for the Raw Logs tool (Section 7.3.1).

7.3.3 Exec Graph

The Exec Graph shows which thread is running at a given time. You can open this tool by choosing **Tools > RTA > Exec Graph** from the CCS menus.

In this graph, square brackets “[]” indicate the beginning and end of Hwi and Swi threads.

 Red flags facing right on the Swi timeline indicate Swi post events.

 Green flags on the Semaphore and Event timelines indicate “post” events, and  red flags facing left indicate “pend” events.

These icons do not indicate which Hwi, Swi, Semaphore, or Event instance the brackets and flags refer to. For this information, group the Exec Graph with the Raw Logs view (they are grouped by default). Then you can click anywhere on the Exec Graph to jump to the corresponding Raw Log record.

This tool contains the following toolbar icons:

 **Toggle Measurement Marker Mode** selects a measuring mode for time marking. The mode choices are "Freeform" or "Snap to Data". The axis choices are X-Axis, Y-Axis, or Both. When you click on the graph, a marker of the type you have selected is placed. When you drag your mouse around the graph, the time is shown in red.

 **Toggle View With Group** setting on and off. (Shift+G)

 **Align Horizontal Center** can be used if you have enabled the View With Group toggle. This icon aligns a group by centering.

 **Align Horizontal Range** can be used if you have enabled the View With Group toggle. This icon aligns a group using a horizontal range.

 Click this icon to **Zoom In** on the graph by spreading out the x-axis.

 Click this icon to **Zoom Out**.

 Choose to **Reset Zoom** level to the default or use the drop-down list to choose a specific zoom level.

 **Refresh** the GUI displays. This button does not collect data from the target.

 Open the **Find In** dialog for searching this graph.

 **Filter** the log records to match a pattern by using the Set Filter Expression dialog.

 **Freeze Data Updates** data updates from the target. This is useful when you are using the Find or Filter dialogs. (Shift+F5)

 **Stream RTA Data** toggles the collection of RTA data at runtime. The default is on if the application is configured to use RTDX. Changing the setting of this toggle affects the setting in all RTA tools.

 **Toggle Autorefresh Mode** is available only when the target is stopped. Toggling this icon on causes the RTA tools to collect stop mode data from the target once per target halt. Changing the setting of this toggle affects the setting in all RTA tools. This mode is on by default.

 **Refresh RTA Buffers in Stop Mode** is available only when the target is stopped, and only when the Autorefresh Mode toggle is off. Clicking this icon causes the RTA tools to collect stop mode data from the target one time.

See Section 7.4.2 and Section 7.4.3 for more about using the , , and  icons.

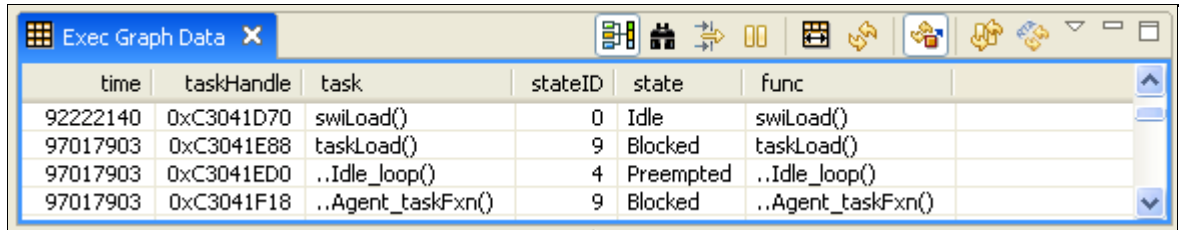

You can right-click on this tool to choose from a menu of options. In addition to some of the toolbar commands, you can use the following additional commands from the right-click menu:

- Legend.** Toggle this command to hide the graph legend.
- Horizontal Axis.** Toggle this command to hide the x-axis time markings.
- Vertical Axis.** Toggle this command to hide the y-axis thread labels.
- Data > Export All.** This command lets you select a .csv (comma-separated value) file to contain all the data currently displayed in the log.
- Groups.** This command lets you define groups to contain various types of log messages.
- Insert Measurement Mark.** Inserts a marker at the location where you right clicked.
- Remove Measurement Mark.** Lets you select a marker to remove.
- Remove All Measurement Marks.** Removes all markers you have placed.
- Display Properties.** Opens a dialog that lets you change the colors, scales, display formats, and labels on the graph.
- RTA Time Unit.** Choose between displaying units for the x axis in ticks or time (ns).

7.3.4 Exec Graph Data

The Exec Graph Data tool is a convenient way to view all the thread-related logs. By default, the Exec Graph Data tool displays the time, taskHandle, task, stateID, state, and func for each thread-related message.

You can open this tool by choosing **Tools > RTA > Exec Graph Data** from the CCS menu bar.

time	taskHandle	task	stateID	state	func
92222140	0xC3041D70	swiLoad()	0	Idle	swiLoad()
97017903	0xC3041E88	taskLoad()	9	Blocked	taskLoad()
97017903	0xC3041ED0	..Idle_loop()	4	Preempted	..Idle_loop()
97017903	0xC3041F18	..Agent_taskFxn()	9	Blocked	..Agent_taskFxn()

The messages shown in this tool are the raw data used to plot the Exec Graph.

The toolbar icons and right-click menu for the Exec Graph Data tool are the same as for the Raw Logs tool (Section 7.3.1).

7.3.5 CPU Load

The CPU Load tool shows the percentage of time the application is not in the idle loop.

You can open this tool by choosing **Tools > RTA > CPU Load** from the CCS menu bar. See Section 7.2, *Load Module* for details on load statistics.

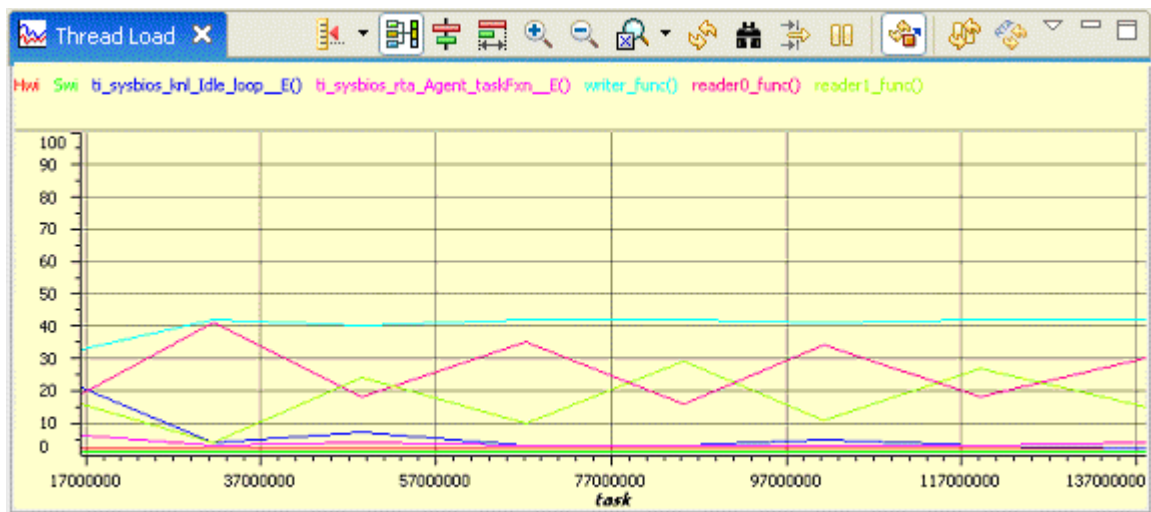

The CPU Load tool has the same toolbar icons and right-click menu as the Exec Graph tool (Section 7.3.3). However, in addition, the following right-click menu commands are provided:

- Show Grid Lines.** Toggle on or off the x-axis and y-axis grid lines you want to see.
- Display As.** Choose the marker you want to use to display the data. The default is a connected line, but you can choose from various marker styles and sizes.
- Auto Scale.** Scales the load data to fit the range in use. For example, if the range is between 70% and 90%, it zooms in on that range to make changes more visible. When auto scale is turned on, the scale may change as new data arrives.
- Reset Auto Scale.** Resets the scale to better display the current data.

7.3.6 Thread Load

The Thread Load tool shows the percentage of time the application spend in each thread.

You can open this tool by choosing **Tools > RTA > Thread Load** from the CCS menu bar. See Section 7.2, *Load Module* for details on load statistics.

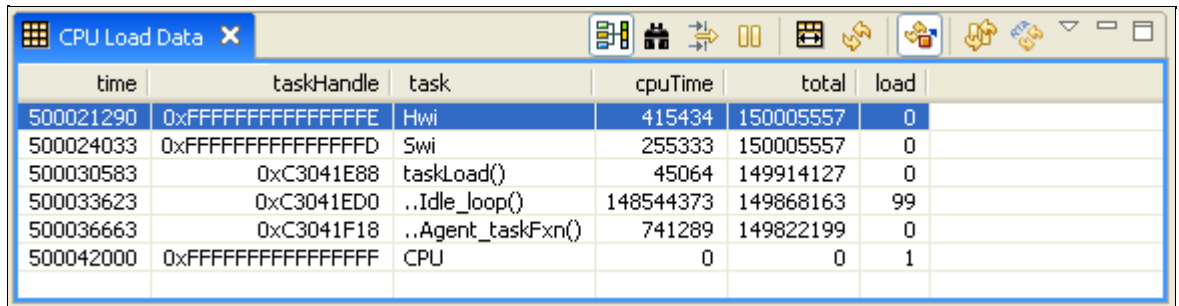

The toolbar icons and right-click menu for the Thread Load tool are the same as for the Exec Graph tool (Section 7.3.3).

7.3.7 CPU Load Data

The CPU Load Data tool is a convenient way to view CPU load-related logs. By default, the CPU Load Data tool displays the time, taskHandle, task, cpuTime, total, and load for each load-related message.

Open this tool by choosing **Tools > RTA > CPU Load Data** from the CCS menu bar.

time	taskHandle	task	cpuTime	total	load
500021290	0xFFFFFFFFFFFFFFFE	Hwi	415434	150005557	0
500024033	0xFFFFFFFFFFFFFFFD	Swi	255333	150005557	0
500030583	0xC3041E88	taskLoad()	45064	149914127	0
500033623	0xC3041ED0	..Idle_loop()	148544373	149868163	99
500036663	0xC3041F18	..Agent_taskFxn()	741289	149822199	0
500042000	0xFFFFFFFFFFFFFFF	CPU	0	0	1

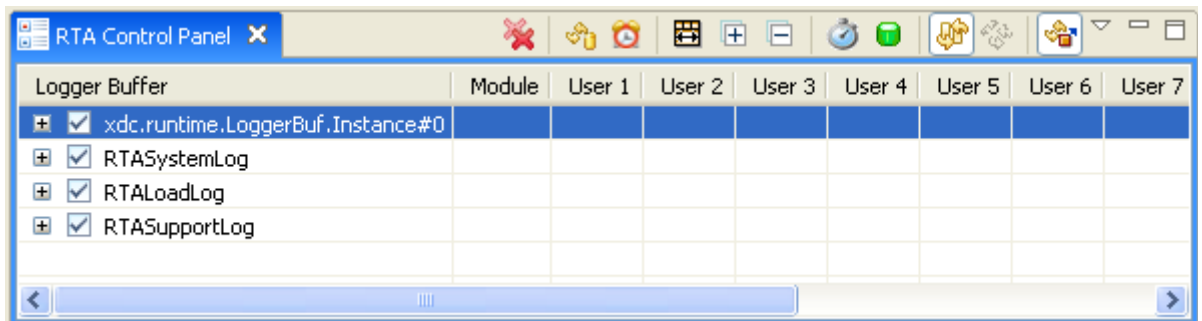

The messages in this tool are raw data used to plot the CPU Load graph.

The toolbar icons and right-click menu for the Load Data tool are the same as for the Raw Logs tool (Section 7.3.1).

7.3.8 RTA Control Panel

The RTA Control Panel provides access to some general RTA settings and gives you control over which Log events are logged on the target.

You can open this panel by choosing **Tools > RTA > RTA Control Panel** from the CCS menu bar.

Logger Buffer	Module	User 1	User 2	User 3	User 4	User 5	User 6	User 7
<input checked="" type="checkbox"/> xdc.runtime.LoggerBuf.Instance#0								
<input checked="" type="checkbox"/> RTASystemLog								
<input checked="" type="checkbox"/> RTALoadLog								
<input checked="" type="checkbox"/> RTASupportLog								

The RTA Control Panel contains the following toolbar icons:

Close All RTA Views, including this one.

Refresh Runtime Configuration information gets the current runtime settings for this tool from the target application.

RTA Update Rate sets the minimum wait time between attempts for the Task that collects RTA information and sends it to the host. In practice, the time may be longer than what you specify if the Task needs to wait to run because its priority is lower than that of other threads.

Auto Fit Columns sets the column widths to fit their current contents.

Expand All nodes in the Logger Buffer column.

Collapse All nodes in the Logger Buffer column.

Duration for RTA Streaming sets how long data is sent from the target to the host computer. The duration is in minutes. The default is to stream as long as the target application is running.

Disk Usage Quota is the amount of disk space on the host computer available to the RTA tools for temporary data storage. The default is 2 GB. This button will take you to the CCS Preferences dialog to set the size and location of these temporary files.

Toggle Autorefresh Mode is available only when the target is stopped. Toggling this icon on causes the RTA tools to collect stop mode data from the target once per target halt. Changing the setting of this toggle affects the setting in all RTA tools.

Refresh RTA Buffers in Stop Mode is available only when the target is stopped, and only when the Autorefresh Mode toggle is off. Clicking this icon causes the RTA tools to collect stop mode data from the target one time.

Stream RTA Data toggles the collection of RTA data at runtime. The default is on if the application is configured to use RTDX. Changing the setting of this toggle affects the setting in all RTA tools.

See Section 7.4.2 and Section 7.4.3 for more about using the , , and  icons.

The RTA Control Panel lets you make runtime changes to the types of Log events that are logged on the target. This allows you to make better use of limited buffer sizes and transport bandwidth and to focus on the events that are currently important to you.

The RTA Control Panel provides control over logging in two ways:

- ❑ You can enable or disable particular LoggerBuf instances
- ❑ You can enable or disable specific Diags levels on a per-module basis.

The RTA Control Panel lists the LoggerBuf instances in the left column. If a name was given to the instance, that name is shown. Otherwise, a LoggerBuf instance is labeled with its address.

Click on a LoggerBuf instance name to see a drop-down menu that allows you to enable or disable that instance. Disabling a LoggerBuf instance means that when the target calls `Log_write()` or `Log_print()` to that LoggerBuf, the record will not actually be written into the buffer—any record written to a disabled LoggerBuf is discarded.

Expanding a LoggerBuf instance shows you the list of modules that are logging to that buffer. For each module you can see the current Diags settings for that module (See <http://rtsc.eclipse.org/cdoc-tip/xdc/runtime/Diags.html> for an explanation of Diags levels and settings). If the checkmark or checkbox is gray, that item is configured as ALWAYS_ON or ALWAYS_OFF.

If a particular Diags level is configured as "RUNTIME_OFF" or "RUNTIME_ON", then you can enable or disable that particular Diags level for a given module. Click on the Diags setting to see a drop-down menu that lets you to turn the level on or off. (You may need to make the columns wider before you can open the drop-down list of settings.)

Note: Modifying log settings requires a data transport. Changing settings in the RTA Control Panel is not possible if your configuration sets the `Agent.transport` property to `Agent.Transport_STOP_MODE_ONLY`.

If you know you will never be interested in receiving a particular set of events, you may want to disable them in your application's configuration by setting them to ALWAYS_OFF. (If your configuration uses the Agent module to

automatically configure logging, you can still change individual Diags levels, and your settings will override those of the Agent. See http://rtsc.eclipse.org/docs-tip/Using_xdc.runtime_Logging for information.)

If you used the RTA Agent to configure system logging for your application, you should see three LoggerBuf instances whose labels begin with "RTA":

- ❑ **RTASystemLog** is a large buffer that holds all system log records from modules such as Hwi, Swi, Task, Idle, Clock, Event, Semaphore, and Timer. See the documentation for each of these modules for details on the events they log. The RTA tools use User1 and User2 logging for this LoggerBuf.
- ❑ **RTALoadLog** is a separate log that holds the Load module records. These records are logged relatively infrequently, but are required to support the CPU and Thread Load graphs. They are sent to a dedicated LoggerBuf instance so that they are not overwritten by other more frequent events. The RTA tools use User4 logging for this LoggerBuf.
- ❑ **RTASupportLog** is used internally by RTA. It is used to log a single record when the application starts to provide RTA with the Timestamp frequency so that timestamps can be converted into seconds.

7.4 RTA Agent

This section describes the `ti.sysbios.rta.Agent` module, which supports the RTA tool in Code Composer Studio 4.x. For information on the RTA tools in CCS 4, see Section 7.3.

The `ti.sysbios.rta.Agent` module is responsible for transmitting Log records from the target to the host for use by the RTA tool. This is accomplished using a `ti.sysbios.knl.Task` instance that is periodically awoken to send all the Log records to the host.

The RTA Agent operates on each of the `xdc.runtime.LoggerBuf` instances in the system in turn. It transmits all available Log records from a given LoggerBuf to the host before servicing the next LoggerBuf instance. In the event that records are being written to a LoggerBuf faster than they are being read, the Agent sends a limited number of records (roughly the size of the LoggerBuf) before moving on to the next LoggerBuf.

The RTA Agent is designed to work with a number of transports, such as TCP/IP, RTDX (see Section 7.4.1), or in stop-mode (at breakpoints in CCS). Configuring the transport is your responsibility, since the transport may be configured for other purposes besides RTA.

7.4.1 Configuring the RTA Agent and RTDX

Real Time Data eXchange (RTDX) allows you to "non-intrusively" pass data from a target application to a host application and vice versa.

You can use the following code as a template for a simple configuration of RTA support using RTDX as the transport:

```
/* Bring in and configure the RTA Agent */
var Agent = xdc.useModule('ti.sysbios.rta.Agent');

/* Have the Agent auto-configure RTDX */
Agent.transport = Agent.Transport_RTDX;
```

Alternately, you can set the transport to Transport_USER (if your application has a custom data gathering setup) or Transport_STOP_MODE_ONLY.

DSP/BIOS 5.x configurations required significantly more statements to configure RTDX. These are no longer needed if you set the Agent.transport property.

In the configuration editor, you can examine the properties of the ti.sysbios.rta.Agent and ti.rtdx.RtdxModule modules. For example, the following statement sets the priority of the Task used by the Agent to collect log information to a higher priority than an example Task called "taskLoadTask".

```
Agent.priority = taskLoadTask.priority + 1;
```

The following statement sets the size of the buffer used to hold log messages before transferring them to the host:

```
Agent.numSystemRecords = 2048;
```

For more examples of statements used to configure the Agent, create a CCS project and use the "RTA Example" template.

By default, the target is expected to be a hardware target with a JTAG connection to the host. If your target is a simulator, your configuration should include the following lines:

```
var RtdxModule = xdc.useModule('ti.rtdx.RtdxModule');
RtdxModule.protocol = RtdxModule.PROTOCOL_SIMULATION;
```

For more information, see the CDOC online documentation for the ti.rtdx package in SYS/BIOS and the TI Embedded Processors Wiki at www.tiexpressdsp.com.

7.4.2 Getting Log Data from a Running Target

If you set the Agent.transport property to Transport_RTDX, you can get RTA information either at runtime or in Stop Mode (see Section 7.4.3).

When you use Transport_RTDX, the RTA Agent creates a Task thread in the target application. That thread gathers all the log records stored in the different LoggerBuf instances on the target.

If the  icon is toggled on in the RTA tools, the Agent sends these records to the host over RTDX automatically. This means that in order for records to be collected and sent to the host via the Agent, the target must be running.

When the target halts, the RTA tools show all the records that the RTA Agent has sent thus far. This typically doesn't include the most recent records, though, since those haven't been collected and sent yet. This may be a problem if you need to see the most recent messages for debugging purposes. This problem is the reason for also supporting Stop Mode updates.

7.4.3 Getting Log Data from a Halted Target

When the target is halted, you can get RTA information from the target (in Stop Mode) if you set the Agent.transport property to either Transport_RTDX or Transport_STOP_MODE_ONLY.

If you set the Agent.transport property to Transport_STOP_MODE_ONLY, the Agent's Task thread for gathering log records is not created, and you can use the RTA tools in Stop Mode but not in Run Mode.

When you use a Stop Mode refresh, the RTA tools read the memory locations of the LoggerBufs on the halted target to get all the log records and add them to the RTA tool displays.

The  icon toggles whether an auto-refresh of Stop Mode data happens when the target halts. This auto-refresh is on by default. However, reading the target's LoggerBuf buffers via the host can be slow, especially for larger buffer sizes, so you may not always want to use this Auto-Refresh capability.

The RTA tools do not show whether they are still collecting data when the target is halted. You can find out how long it takes to collect the LoggerBuf records for your application by opening the ROV tool, moving to the xdc.runtime.LoggerBuf module, and choosing the Records tab. The data acquisition time for these records in the ROV tool should be the same as the time needed to refresh the RTA tools in Stop Mode.

If the update takes a long time for your application, you can use the  icon to manually trigger a refresh when the target halts and you want to see the latest data in the target's LoggerBufs.

7.4.4 Automatic System Logging Configuration

By default, the Agent module automatically configures logging for all the modules needed by the RTA tool. The RTA tool expects all logs from the following modules to be logged to a single LoggerBuf instance with the instance name "RTASystemLog":

- ti.sysbios.knl
 - Clock
 - Idle
 - Swi
 - Task
 - Event
 - Semaphore
- ti.sysbios.family.*
 - Hwi
 - Timer
- ti.sysbios.utils
 - Load

For all of these modules except Load, the Agent sets `diags_USER1` and `diags_USER2` to `RUNTIME_ON`. For the Load module, it sets `diags_USER4` to `RUNTIME_ON`.

To change any of these settings (for example, to set the diags to `ALWAYS_ON`), set `Agent.configureSystemLog` to `false` and perform the configuration manually. To perform the configuration manually, create a `LoggerBuf` instance and give it the instance name "RTASystemLog". Ensure that all of the above modules log to this "RTASystemLog" `LoggerBuf`.

7.5 Performance Optimization

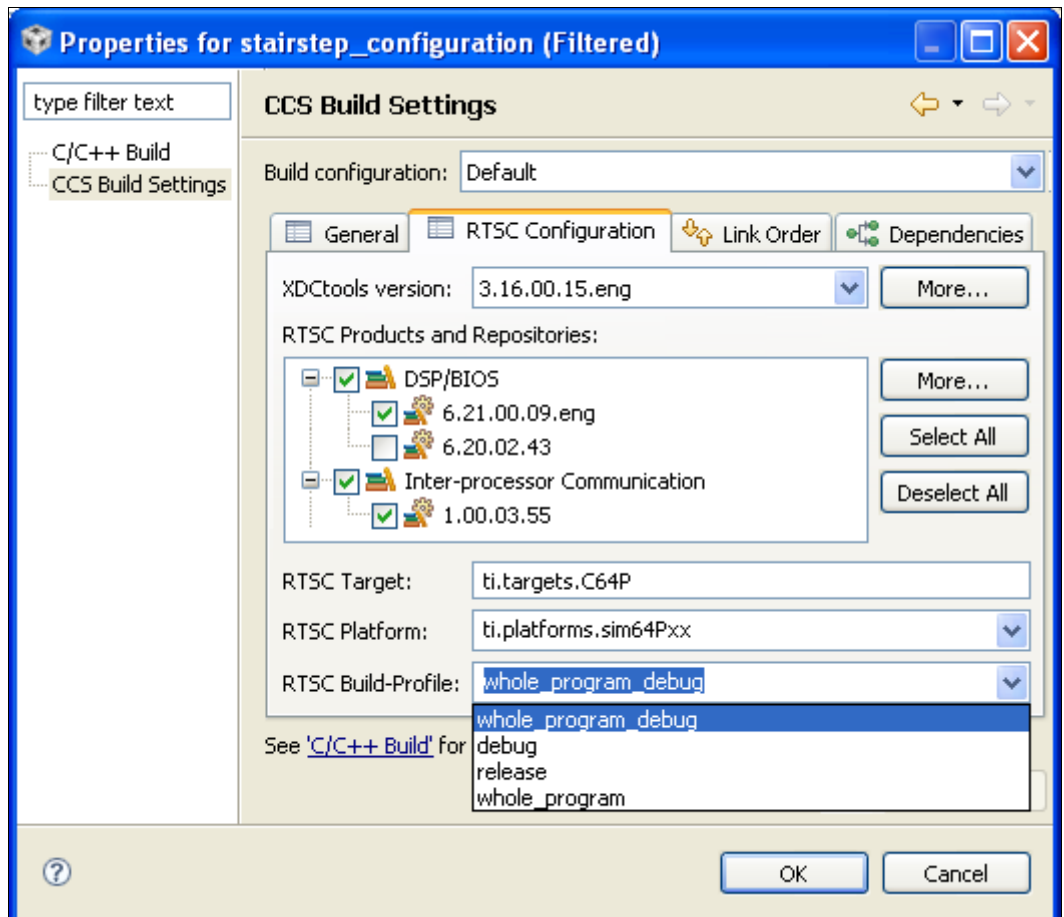

This section provides tips and suggestions for optimizing the performance of a SYS/BIOS-based application. This is accomplished in two ways: by using compiler and linker optimizations, and by optimizing the configuration of SYS/BIOS.

7.5.1 Whole-Program Optimization

Whole-program optimization is a compiler optimization technique that enables the compiler to look across multiple source files when generating object code.

This optimization is central to the promise of RTSC's ability to provide flexibility during configuration without sacrificing system performance. Given an application's configuration, RTSC generates a C file that contains many initialized constants and small code fragments (often "glue" code). Using whole-program optimization, all of these items will typically be removed from the final executable image through classic optimizations such as constant folding and function inlining. Whole-program optimization allows this to occur across independent module boundaries.

Whole-program optimization increases the time to build an application, but improves the application's performance dramatically. To build a configuration project with whole-program optimization, choose "whole_program" or "whole_program_debug" in the RTSC Build-Profile field of the RTSC Configuration tab of the CCS Build Settings dialog.

The "whole_program_debug" profile preserves enough debug information to make it still possible to step through the optimized code in CCS and locate global variables. In SYS/BIOS performance benchmark testing, applications compiled with "whole_program_debug" have been found to have performance that matches that of "whole_program", so it is recommended that you use whole_program_debug.

7.5.2 Configuring Logging

Logging can significantly impact the performance of a system. You can reduce the impact of logging by optimizing the configuration. There are two main ways to optimize the logging used in your application:

- ❑ **No logging.** In SYS/BIOS, logging is not enabled by default. However, if you enable the `ti.sysbios.rta.Agent` module as described in Section 7.4.1, logging is performed for all SYS/BIOS system modules. To configure your application without logging support, do not enable the RTA Agent, and no logging will occur by default.
- ❑ **Optimizing logging.** If you need some logging enabled in your application, there are some configuration choices you can make to optimize performance. These are described in the following subsections.

7.5.2.1 Diags Settings

There are four diagnostics settings for each diagnostics level: `RUNTIME_OFF`, `RUNTIME_ON`, `ALWAYS_OFF`, and `ALWAYS_ON`.

The two runtime settings (`RUNTIME_OFF` and `RUNTIME_ON`) allow you to enable or disable a particular diagnostics level at runtime. However, a check must be performed to determine whether logging is enabled or disabled every time an event is logged.

If you use `ALWAYS_OFF` or `ALWAYS_ON` instead, you will not be able to change the setting at runtime, but the logging call will either be a direct call to log the event (`ALWAYS_ON`) or will be optimized out of the code altogether (`ALWAYS_OFF`).

```
var Defaults = xdc.useModule('xdc.runtime.Defaults');
var Diags = xdc.useModule('xdc.runtime.Diags');

/* 'RUNTIME' settings allow you to turn it off or on at runtime,
 * but require a check at runtime. */
Defaults.common$.diags_USER1 = Diags.RUNTIME_ON;
Defaults.common$.diags_USER2 = Diags.RUNTIME_OFF;

/* These settings cannot be changed at runtime, but optimize out
 * the check for better performance. */
Defaults.common$.diags_USER3 = Diags.ALWAYS_OFF;
Defaults.common$.diags_USER4 = Diags.ALWAYS_ON;
```

7.5.2.2 Choosing Diagnostics Levels

SYS/BIOS modules only log to two levels: USER1 and USER2. They follow the convention that USER1 is for basic events and USER2 is for more detail.

To improve performance, you could only turn on USER1, or turn on USER2 for particular modules only.

Refer to each module's documentation to see which events are logged as USER1 and which are logged as USER2.

7.5.2.3 Choosing Modules to Log

To optimize logging, enable logging only for modules that interest you for debugging.

For example, Hwi logging tends to be the most expensive in terms of performance due to the frequency of hardware interrupts. Two Hwi events are logged on every Clock tick when the Clock's timer expires.

7.5.3 Configuring Diagnostics

By default, ASSERTS are enabled for all modules. SYS/BIOS uses asserts to check for common user mistakes such as calling an API with an invalid argument or from an unsupported context. Asserts are useful for catching coding mistakes that may otherwise lead to confusing bugs.

To optimize performance after you have done basic debugging of API calls, your configuration file can disable asserts as follows:

```
var Defaults = xdc.useModule('xdc.runtime.Defaults');
var Diags = xdc.useModule('xdc.runtime.Diags');

/* Disable asserts in all modules. */
Defaults.common$.diags_ASSERT = Diags.ALWAYS_OFF;
```

7.5.4 Choosing a Heap Manager

SYS/BIOS provides three different heap manager implementations: HeapMem, HeapBuf, and HeapMultiBuf. Each of these has various performance trade-offs when allocating and freeing memory.

HeapMem can allocate a block of any size, but is the slowest of the three. HeapBuf can only allocate blocks of a single configured size, but is very quick. HeapMultiBuf manages a pool of HeapBuf instances and balances the advantages of the other two. HeapMultiBuf is quicker than HeapMem, but slower than HeapBuf.

See the documentation for each of these modules for a detailed discussion of the trade-offs of each module.

Consider also using different heap implementations for different roles. For example, `HeapBuf` is ideally suited for allocating a fixed-size object that is frequently created and deleted. If you were creating and deleting many `Task` instances, you could create a `HeapBuf` instance just for allocating `Tasks`.

7.5.5 Hwi Configuration

The hardware interrupt dispatcher provides a number of features by default that add to interrupt latency. If your application does not require some of these features, you can disable them to reduce interrupt latency.

- ❑ **`dispatcherAutoNestingSupport`.** You may disable this feature if you don't need interrupts enabled during the execution of your Hwi functions.
- ❑ **`dispatcherSwiSupport`.** You may disable this feature if no Swi threads will be posted from any Hwi threads.
- ❑ **`dispatcherTaskSupport`.** You may disable this feature if no APIs are called from Hwi threads that would lead to a `Task` being scheduled. For example, `Semaphore_post()` would lead to a `Task` being scheduled.
- ❑ **`dispatcherIrpTrackingSupport`.** This feature supports the `Hwi_getIrp()` API, which returns an interrupt's most recent return address. You can disable this feature if your application does not use that API.

7.5.6 Stack Checking

By default, the `Task` module checks to see whether a `Task` stack has overflowed at each `Task` switch. To improve `Task` switching latency, you can disable this feature the `Task.checkStackFlag` property to `false`.

SYS/BIOS Emulation on Windows

This appendix describes SYS/BIOS emulation when using the Microsoft Windows operating system.

Topic	Page
A.1 Motivation	A-2
A.2 High-Level Description	A-2
A.3 Clock Rate Considerations	A-4

A.1 Motivation

You can use SYS/BIOS emulation on Windows to model your SYS/BIOS applications on a high-level operating system before moving to simulators or hardware.

When you are developing a software module, such as a codec, a common practice is to first write a "Golden C" version. Once the software module is functioning properly, the Golden C version is used as a baseline for porting the software to specific target platforms.

When developing the Golden C version, it is often preferable to do this work on a High-Level Operating System (HLOS), such as Windows. This allows the use of HLOS tool-chains for code profiling and validation. Providing a SYS/BIOS Emulation layer that runs on Windows makes this effort more efficient. It allows a native SYS/BIOS application to be built and run as a native Windows executable.

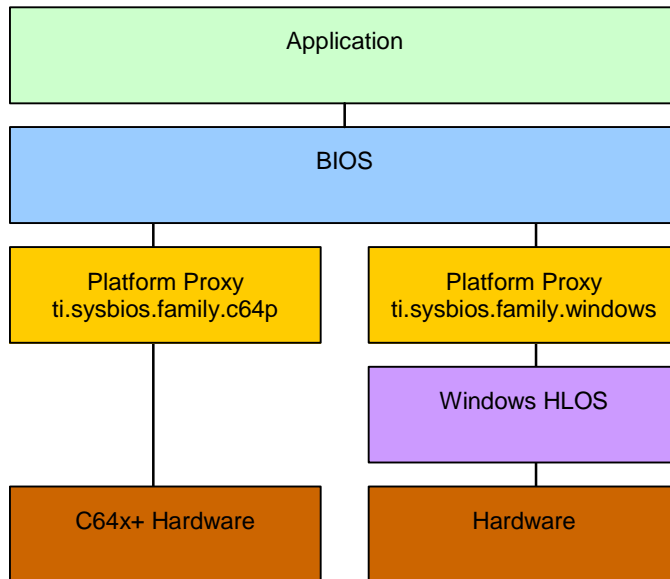

A.2 High-Level Description

SYS/BIOS emulation is supported by implementing the platform proxy modules for Windows. These modules are contained in the `ti.sysbios.family.windows` package. These proxy modules provide interfaces for the following:

- ❑ hardware interrupts
- ❑ thread context switching
- ❑ general purpose timers
- ❑ system clock tick counter

To implement these interfaces, some hardware functionality is emulated in the proxy modules because Windows does not allow direct access to the hardware.

The following figure shows a block diagram of both a 'C64x+ implementation and a Windows implementation.

Application code written in C that makes only SYS/BIOS API calls should not require any changes. However, any code written for peripheral control will need to be replaced. Peripherals are not modeled in the emulation package.

The SYS/BIOS Kernel does not require any changes. Through XDCtools configuration, the kernel binds with the appropriate proxy modules relevant to the target platform (that is, for the Windows platform or a hardware platform).

When building the application, XDCtools configuration is used to select the runtime platform. Through configuration options, the application can bind with the appropriate modules that are hardware or emulation specific. This will most likely pertain to peripheral and/or test framework code.

On hardware platforms, peripheral devices typically raise interrupts to the CPU, which then invokes the Hwi dispatcher to service the interrupt. To emulate this behavior, the SYS/BIOS Emulation package simulates an interrupt that preempts the currently running task and invokes the Hwi Dispatcher. This is done asynchronously with respect to SYS/BIOS tasks.

The Windows Emulation package faithfully emulates the SYS/BIOS scheduler behavior. That is to say that task scheduling will occur in the same order on Windows as on hardware. However, interrupts are not real-time. Therefore, interrupt preemption will differ, and this may invoke the scheduler in a different sequence than observed when running on hardware.

Windows Win32 API functions may be invoked along side SYS/BIOS API functions. This should be kept to a minimum in order to encourage code encapsulation and to maximize code reuse between hardware and the Windows platforms.

A.3 Clock Rate Considerations

When running on Windows Emulation, the SYS/BIOS clock is configured to tick much slower. This is necessary because the Windows clock ticks slower than a typical hardware clock. Thus, any code that depends on clock ticks, instead of wall clock duration, should take this into account in the configuration phase.

For example, if `Task_sleep(500)` is called on a hardware platform where the SYS/BIOS clock ticks every 1 millisecond (resulting in a 500 millisecond sleep period), then it should be normalized for the Windows platform using the following formula:

$$\text{windowsTicks} = 500 / (\text{Clock_tickPeriod} / 1000)$$

where the `Clock_tickPeriod` is the SYS/BIOS clock tick period on Windows.

Rebuilding SYS/BIOS

This appendix describes how to rebuild the SYS/BIOS source code.

Topic	Page
B.1 Overview.....	B-2
B.2 Prerequisites	B-2
B.3 Build Procedure.....	B-2
B.4 Building Your Project Using a Rebuilt SYS/BIOS.....	B-4

B.1 Overview

The SYS/BIOS product includes source files and RTSC build scripts that allow you to modify the SYS/BIOS sources and rebuild its libraries. You can do this in order to modify, update, or add functionality.

If you edit the SYS/BIOS source code and/or corresponding RTSC build scripts, you must also rebuild SYS/BIOS in order to create new libraries containing these modifications.

The instructions in this appendix are tailored for rebuilding on Microsoft Windows. However, SYS/BIOS may also be re-built on Linux using these instructions by changing the DOS commands and paths to the equivalents for Linux.

Warning: This appendix provides details about rebuilding the SYS/BIOS source code. We strongly recommend that you copy the SYS/BIOS installation to a directory with a different name and rebuild that copy, rather than rebuilding the original installation.

B.2 Prerequisites

In order to rebuild SYS/BIOS, the SYS/BIOS, XDCtools, and IPC products must be installed. The IPC installation location must be referenced in the definition of the XDCPATH environment variable.

It is important to build SYS/BIOS with compatible versions of XDCtools and IPC. To find out which versions are compatible, see the “Dependencies” section of the Release Notes in the top-level directory of your SYS/BIOS installation.

B.3 Build Procedure

Follow these steps to rebuild the SYS/BIOS source code:

- 1) Create a new directory on your computer that you will use to store a copy of the SYS/BIOS installation. This directory will act as a container for your own SYS/BIOS modifications.

The full path to this directory cannot contain any spaces. For example, we recommend making a directory called "C:\myBiosBuilds" rather than using a location in the “My Documents” directory tree.

- 2) Using Windows Explorer, copy the entire SYS/BIOS installation into the directory you just created. For example, if you installed SYS/BIOS in the default installation location, then you should copy the following folder and all of its contents:

```
C:\Program Files\Texas Instruments\bios_6_30_##_##  
into the folder:
```

```
C:\myBiosBuilds
```

After this step, the folder C:\myBiosBuilds should contain the folder bios_6_30_##_##, which is a copy of your SYS/BIOS installation.

- 3) Rename the folder that contains the copy of SYS/BIOS. For example, rename the following directory:

```
C:\myBiosBuilds\bios_6_30_##_##  
to:
```

```
C:\myBiosBuilds\custom_bios_6_30_##_##
```

- 4) Copy the file "config.bld.default" from the "etc" folder of your original SYS/BIOS installation into the "packages" folder of the copy of the SYS/BIOS installation you just made. For example, copy:

```
C:\Program Files\Texas Instruments\bios_6_30_##_##  
\etc\config.bld.default
```

to the following location:

```
C:\myBiosBuilds\custom_bios_6_30_##_##\packages
```

- 5) Rename the copied "config.bld.default" file to be "biosConfig.bld".
- 6) Open the biosConfig.bld file for text editing.
- 7) Near the end of the file, look for the array called "Build.targets". This array contains the list of targets for which SYS/BIOS should be built. Ensure that the target for which you want SYS/BIOS built is uncommented. For example, if you want to build SYS/BIOS for the C64P target only, then your Build.targets array would look like this:

```
Build.targets = [  
    //C28_large,  
    C64P,  
    //C67P, //setup elf compiler path at top of page  
    //C674,  
    //Arm9,  
    //M3,  
    //MSP430,  
    //Win32,  
];
```

- 8) Save and exit the file. You are now ready to rebuild SYS/BIOS.
- 9) Open a DOS command prompt window.
- 10) If you have not already added IPC to your XDCPATH environment variable, do so now. For example, Type:

```
set XDCPATH=%XDCPATH%;C:/Program Files/  
Texas Instruments/ipc_1_##_##_##/packages
```

- 11) Change directories to the location of your copy of SYS/BIOS. For example:

```
cd C:\myBiosBuilds\custom_bios_6_30_##_##\packages
```

- 12) Build SYS/BIOS using the biosConfig.bld file as follows:

```
xdc XDCBUILDCFG=./biosConfig.bld -PR .
```

If you want to clear out intermediate and output files from a previous build, you can use the following command

```
xdc clean
```

For details about the XDCPATH environment variable, see http://rtsc.eclipse.org/docs-tip/Managing_the_Package_Path in the RTSC-pedia. For more about the “xdc” command line, see http://rtsc.eclipse.org/docs-tip/Command_-_xdc.

B.4 Building Your Project Using a Rebuilt SYS/BIOS

To build your application using the version of SYS/BIOS you have rebuilt, you must point your project to this rebuilt version by following these steps:

- 1) Open CCSv4 and select the application project you want to rebuild.
- 2) Right-click on your project and choose **Build Properties**. If you have a RTSC configuration project that is separate from your application project, open the build properties for the configuration project.
- 3) In the **CCS Build** category of the Properties dialog, choose the **RTSC** tab.

- 4) Under the **Products and Repositories** tab, uncheck *all* the boxes for SYS/BIOS (and DSP/BIOS if there are any). This ensures that no version is selected.

- 5) Click the **Add** button next to the **Products and Repositories** tab.
- 6) Choose **Select repository from file-system**, and browse to the “packages” directory of the location where you copied and rebuilt SYS/BIOS. For example, the location may be C:\myBiosBuilds\custom_bios_6_30_##-##\packages.

Please select the RTSC product version. Alternatively, browse to a product or repository location in the file-system. This product/repository will automatically be registered for future use.

Product version

Select product version: DSP/BIOS 6.30.00.18.eng

Select product from file-system: Browse...

Select repository from file-system: C:\myRepository\custom_bios_6_30\packages Browse..

- 7) Click **OK** to apply these changes to the project.
- 8) You may now rebuild your project using the re-built version of SYS/BIOS.

Timing Benchmarks

This appendix describes SYS/BIOS timing benchmark statistics.

Topic	Page
C.1 Timing Benchmarks	C-2
C.2 Interrupt Latency	C-2
C.3 Hwi-Hardware Interrupt Benchmarks	C-2
C.4 Swi-Software Interrupt Benchmarks	C-4
C.5 Task Benchmarks	C-5
C.6 Semaphore Benchmarks	C-8

C.1 Timing Benchmarks

This appendix describes the timing benchmarks for SYS/BIOS functions, explaining the meaning of the values as well as how they were obtained, so that designers may better understand their system performance.

The sections that follow explain the meaning of each of the timing benchmarks. The name of each section corresponds to the name of the benchmark in the actual benchmark data table.

The explanations in this appendix are best viewed along side the actual benchmark data. Since the actual benchmark data depends on the target and the memory configuration, and is subject to change, the data is provided in HTML files in the ti.sysbios.benchmarks package (that is, in the BIOS_INSTALL_DIR\packages\ti\sysbios\benchmarks directory).

C.2 Interrupt Latency

The Interrupt Latency benchmark is the maximum number of instructions during which the SYS/BIOS kernel disables maskable interrupts. Interrupts are disabled in order to modify data shared across multiple threads. SYS/BIOS minimizes this time as much as possible to allow the fastest possible interrupt response time.

The interrupt latency of the kernel is measured across the scenario within SYS/BIOS in which maskable interrupts will be disabled for the longest period of time. The measurement provided here is the cycle count measurement for executing that scenario.

C.3 Hwi-Hardware Interrupt Benchmarks

Hwi_enable(). This is the execution time of a Hwi_enable() function call, which is used to globally enable hardware interrupts.

Hwi_disable(). This is the execution time of a Hwi_disable() function call, which is used to globally disable hardware interrupts.

Hwi dispatcher. These are execution times of specified portions of Hwi dispatcher code. This dispatcher handles running C code in response to an interrupt. The benchmarks provide times for the following cases:

- ❑ **Interrupt prolog for calling C function.** This is the execution time from when an interrupt occurs until the user's C function is called.
- ❑ **Interrupt epilog following C function call.** This is the execution time from when the user's C function completes execution until the Hwi dispatcher has completed its work and exited.

Hardware interrupt to blocked task. This is a measurement of the elapsed time from the start of an ISR that posts a semaphore, to the execution of first instruction in the higher-priority blocked task, as shown in Figure C-1.

Figure C-1 Hardware Interrupt to Blocked Task

Hardware interrupt to software interrupt. This is a measurement of the elapsed time from the start of an ISR that posts a software interrupt, to the execution of the first instruction in the higher-priority posted software interrupt.

This duration is shown in Figure C-2. Swi 2, which is posted from the ISR, has a higher priority than Swi 1, so Swi 1 is preempted. The context switch for Swi 2 is performed within the Swi executive invoked by the Hwi dispatcher, and this time is included within the measurement. In this case, the registers saved/restored by the Hwi dispatcher correspond to that of "C" caller saved registers.

Figure C-2 Hardware Interrupt to Software Interrupt

C.4 Swi-Software Interrupt Benchmarks

Swi_enable(). This is the execution time of a Swi_enable() function call, which is used to enable software interrupts.

Swi_disable(). This is the execution time of a Swi_disable() function call, which is used to disable software interrupts.

Swi_post(). This is the execution time of a Swi_post() function call, which is used to post a software interrupt. Benchmark data is provided for the following cases of Swi_post():

- ❑ **Post software interrupt again.** This case corresponds to a call to Swi_post() of a Swi that has already been posted but hasn't started running as it was posted by a higher-priority Swi. Figure C-3 shows this case. Higher-priority Swi1 posts lower-priority Swi2 twice. The cycle count being measured corresponds to that of second post of Swi2.

Figure C-3 Post of Software Interrupt Again

- ❑ **Post software interrupt, no context switch.** This is a measurement of a Swi_post() function call, when the posted software interrupt is of lower priority than currently running Swi. Figure C-4 shows this case.

Figure C-4 Post Software Interrupt without Context Switch

- ❑ **Post software interrupt, context switch.** This is a measurement of the elapsed time between a call to `Swi_post()` (which causes preemption of the current `Swi`) and the execution of the first instruction in the higher-priority software interrupt, as shown in Figure C-5. The context switch to `Swi2` is performed within the `Swi` executive, and this time is included within the measurement.

Figure C-5 Post Software Interrupt with Context Switch

C.5 Task Benchmarks

Task_enable(). This is the execution time of a `Task_enable()` function call, which is used to enable SYS/BIOS task scheduler.

Task_disable(). This is the execution time of a `Task_disable()` function call, which is used to disable SYS/BIOS task scheduler.

Task_create(). This is the execution time of a `Task_create()` function call, which is used to create a task ready for execution. Benchmark data is provided for the following cases of `Task_create()`:

- ❑ **Create a task, no context switch.** The executing task creates and readies another task of lower or equal priority, which results in no context switch. See Figure C-6.

Figure C-6 Create a New Task without Context Switch

- ❑ **Create a task, context switch.** The executing task creates another task of higher priority, resulting in a context switch. See Figure C–7.

Figure C–7 Create a New Task with Context Switch

Note: The benchmarks for `Task_create()` assume that memory allocated for a Task object is available in the first free list and that no other task holds the lock to that memory. Additionally the stack has been pre-allocated and is being passed as a parameter.

Task_delete(). This is the execution time of a `Task_delete()` function call, which is used to delete a task. The Task handle created by `Task_create()` is passed to the `Task_delete()` API.

Task_setpri(). This is the execution time of a `Task_setpri()` function call, which is used to set a task's execution priority. Benchmark data is provided for the following cases of `Task_setpri()`:

- ❑ **Set a task priority, no context switch.** This case measures the execution time of the `Task_setpri()` API called from a task Task1 as in Figure C–8 if the following conditions are all true:
 - `Task_setpri()` sets the priority of a lower-priority task that is in ready state.
 - The argument to `Task_setpri()` is less then the priority of current running task.

Figure C–8 Set a Task's Priority without a Context Switch

- ❑ **Lower the current task's own priority, context switch.** This case measures execution time of `Task_setpri()` API when it is called to lower the priority of currently running task. The call to `Task_setpri()` would result in context switch to next higher-priority ready task. Figure C–9 shows this case.

Figure C–9 Lower the Current Task's Priority, Context Switch

- ❑ **Raise a ready task's priority, context switch.** This case measures execution time of `Task_setpri()` API called from a task Task1 if the following conditions are all true:
 - `Task_setpri()` sets the priority of a lower-priority task that is in ready state.
 - The argument to `Task_setpri()` is greater than the priority of current running task.

The execution time measurement includes the context switch time as shown in Figure C–10.

Figure C–10 Raise a Ready Task's Priority, Context Switch

- ❑ **Task_yield().** This is a measurement of the elapsed time between a function call to `Task_yield()` (which causes preemption of the current task) and the execution of the first instruction in the next ready task of equal priority, as shown in Figure C–11.

Figure C–11 Task Yield

C.6 Semaphore Benchmarks

Semaphore benchmarks measure the time interval between issuing a `Semaphore_post()` or `Semaphore_pend()` function call and the resumption of task execution, both with and without a context switch.

Semaphore_post(). This is the execution time of a `Semaphore_post()` function call. Benchmark data is provided for the following cases of `Semaphore_post()`:

- ❑ **Post a semaphore, no waiting task.** In this case, the `Semaphore_post()` function call does not cause a context switch as no other task is waiting for the semaphore. This is shown in Figure C–12.

Figure C–12 Post Semaphore, No Waiting Task

- ❑ **Post a semaphore, no context switch.** This is a measurement of a `Semaphore_post()` function call, when a lower-priority task is pending on the semaphore. In this case, `Semaphore_post()` readies the lower-priority task waiting for the semaphore and resumes execution of the original task, as shown in Figure C–13.

Figure C–13 Post Semaphore, No Context Switch

- ❑ **Post a semaphore, context switch.** This is a measurement of the elapsed time between a function call to `Semaphore_post()` (which readies a higher-priority task pending on the semaphore causing a context switch to higher-priority task) and the execution of the first instruction in the higher-priority task, as shown in Figure C–14.

Figure C–14 Post Semaphore with Task Switch

Semaphore_pend(). This is the execution time of a Semaphore_pend() function call, which is used to acquire a semaphore. Benchmark data is provided for the following cases of Semaphore_pend():

- ❑ **Pend on a semaphore, no context switch.** This is a measurement of a Semaphore_pend() function call without a context switch (as the semaphore is available.) See Figure C–15.

Figure C–15 Pend on Semaphore, No Context Switch

- ❑ **Pend on a semaphore, context switch.** This is a measurement of the elapsed time between a function call to Semaphore_pend() (which causes preemption of the current task) and the execution of first instruction in next higher-priority ready task. See Figure C–16.

Figure C–16 Pend on Semaphore with Task Switch

Size Benchmarks

This appendix describes SYS/BIOS size benchmark statistics.

Topic	Page
D.1 Overview.....	D-2
D.2 Comparison to DSP/BIOS 5	D-3
D.3 Default Configuration Sizes	D-4
D.4 Static Module Application Sizes	D-4
D.5 Dynamic Module Application Sizes	D-9
D.6 Timing Application Size	D-9

D.1 Overview

This appendix contains information on the size impact of using SYS/BIOS modules in an application.

Tradeoffs between different SYS/BIOS 6 modules and their impact on system memory can be complex, because applying a module usually requires support from other modules.

Also, even if one module's code is linked in by another module, it does not necessarily link in the entire module, but typically only the functions referenced by the application—an optimization that keeps the overall size impact of the SYS/BIOS 6 kernel to a minimum.

Because of the complexity of these tradeoffs, it is important to understand that this appendix does not provide an analytical model of estimating SYS/BIOS 6 overhead, but rather gives sizing information for a number of SYS/BIOS configurations.

The size benchmarks are a series of applications that are built on top of one another. Moving down Table D–1, each application includes all of the configuration settings and API calls in the previous applications. Applications lower on the table generally require the modules in the applications above them (The Clock module, for example, requires the Hwi module), so this progression allows for measuring the size impact of a module by subtracting the sizes of all of the other modules it depends upon. (The data in the table, however, is provided in absolute numbers.)

The actual size benchmark data is included in the SYS/BIOS 6 installation in the `ti.sysbios.benchmarks` package (that is, in the `BIOS_INSTALL_DIR\packages\ti\sysbios\benchmarks` directory). There is a separate HTML file for each target. For example, the 'C64x sizing information can be found in the `c6400Sizing.html` file.

For each benchmark application, the table provides four pieces of sizing information, all in 8-bit bytes.

- ❑ **Code Size** is the total size of all of the code in the final executable.
- ❑ **Initialized Data Size** is the total size of all constants (the size of the `.const` section).
- ❑ **Uninitialized Data Size** is the total size of all variables.
- ❑ **C-Initialization Size** is the total size of C-initialization records.

The following sections should be read alongside the actual sizing information as a reference.

D.2 Comparison to DSP/BIOS 5

Where possible, SYS/BIOS 6 size benchmarks have been designed to match the DSP/BIOS 5 benchmarks so that the results can be compared directly. The following table shows which data to compare.

Table D–1 Comparison of Benchmark Applications

DSP/BIOS 5	SYS/BIOS 6
Default configuration	Default configuration
Base configuration	Basic configuration
HWI application	Hwi application
CLK application	Clock application
CLK Object application	Clock Object application
SWI application	Swi application
SWI Object application	Swi Object application
PRD application	None ¹
PRD Object application	None ¹
TSK application	Task application
TSK Object application	Task Object application
SEM application	Semaphore application
SEM Object application	Semaphore Object application
MEM application	Memory application
Dynamic TSK application	Dynamic Task application
Dynamic SEM application	Dynamic Semaphore application
RTA application	None ²
None ³	Timing Application

¹ SYS/BIOS 6 does not have a PRD module. Instead, the SYS/BIOS 6 Clock module supports the functionality of both the DSP/BIOS 5 CLK and PRD modules.

² The RTA application is not yet implemented for SYS/BIOS 6.

³ The new benchmark is the application used to generate the timing benchmarks for SYS/BIOS 6 (see Appendix C). This application leverages all of the key components of the operating system in a meaningful way. It does not utilize any of the size-reducing measures employed in the base configuration of the size benchmarks.

D.3 Default Configuration Sizes

There are two minimal configurations provided as base size benchmarks:

- ❑ **Default Configuration.** This is the true "default" configuration of SYS/BIOS. The configuration script simply includes the BIOS module as follows:

```
xdc.useModule('ti.sysbios.BIOS');
```

This shows the size of an empty application with everything left at its default value; no attempts have been made here to minimize the application size.

- ❑ **Basic Configuration.** This configuration strips the application of all unneeded features and is essentially the smallest possible SYS/BIOS application. Appendix E details tactics used to reduce the memory footprint of this configuration. This is the configuration that the size benchmarks will be built off of.

D.4 Static Module Application Sizes

This section is the focus of the size benchmarks. Each application builds on top of the applications above it in Table D-1.

For each module there are generally two benchmarks. For example, there is the "Clock application" benchmark and the "Clock Object application" benchmark.

The first of the two benchmarks (Clock application) does three things:

- 1) In the configuration script, it includes the module.
- 2) In the configuration script, it creates a static instance of the module.
- 3) In the C code, it makes a call to one of the module's APIs.

The second benchmark (the "object" application) creates a second static instance in the configuration script. This demonstrates the size impact of creating an instance of that object. For example, if the Clock application requires x bytes of initialized data, and the Clock Object application requires y bytes of initialized data, then the impact of one Clock instance is $(y - x)$ bytes of data.

The code snippets for each application apply to all targets, except where noted.

D.4.1 Hwi Application

The Hwi Application configuration script creates a Hwi instance, and the C code calls the Hwi_plug() API.

Configuration Script Addition

```
// Use target/device-specific Hwi module.
var Hwi = xdc.useModule('ti.sysbios.family.c64.Hwi');
var hwi5 = Program.global.hwi5 =
    Hwi.create(5, '&oneArgFxn');
```

C Code Addition

```
Hwi_plug(7, (Hwi_PlugFuncPtr)main);
```

D.4.2 Clock Application

The Clock Application enables the Clock module, creates a Clock instance, and pulls in the modules necessary to call the Timestamp_get32() API in the C code.

Configuration Script Addition

```
var BIOS = xdc.useModule('ti.sysbios.BIOS');
BIOS.clockEnabled = true;

var Clock = xdc.useModule('ti.sysbios.knl.Clock');
Clock.create("&oneArgFxn", 5,
    {startFlag:true, arg:10});

xdc.useModule('xdc.runtime.Timestamp');
```

C Code Addition

```
Timestamp_get32();
```

D.4.3 Clock Object Application

The Clock Object Application statically creates an additional Clock instance to illustrate the size impact of each Clock instance.

Configuration Script Addition

```
Clock.create("&oneArgFxn", 5,
    {startFlag:true, arg:10});
```

D.4.4 Swi Application

The Swi Application enables the Swi module and creates a static Swi instance in the configuration script. It calls the Swi_post() API in the C code.

Configuration Script Addition

```
var BIOS = xdc.useModule('ti.sysbios.BIOS');
BIOS.swiEnabled = true;

var Swi = xdc.useModule('ti.sysbios.knl.Swi');
Program.global.swi0 = Swi.create('&twoArgsFxn');
```

C Code Addition

```
Swi_post(swi0);
```

D.4.5 Swi Object Application

The Swi Object Application creates an additional Swi instance to illustrate the size impact of each new Swi instance.

Configuration Script Addition

```
Program.global.swi1 = Swi.create('&twoArgsFxn');
```

D.4.6 Task Application

The Task Application configuration script enables Tasks and creates a Task instance. It also configures the stack sizes to match the sizes in the DSP/BIOS 5 benchmarks (for comparison).

In the C code, the Task application makes a call to the Task_yield() API.

Configuration Script Addition

```
var BIOS = xdc.useModule('ti.sysbios.BIOS');
BIOS.taskEnabled = true;

var Task = xdc.useModule('ti.sysbios.knl.Task');
Program.global.tsk0 = Task.create("&twoArgsFxn");

Task.idleTaskStackSize = 0x200;
Program.global.tsk0.stackSize = 0x200;
```

C Code Addition

```
Task_yield();
```

D.4.7 Task Object Application

The Task Object Application creates an additional Task instance to illustrate the size impact of each new Task instance.

Configuration Script Addition

```
Program.global.tsk1 = Task.create("&twoArgsFxn");  
Program.global.tsk1.stackSize = 0x200;
```

D.4.8 Semaphore Application

The Semaphore Application configuration script creates a Semaphore instance and disables support for Events in the Semaphore for an equitable comparison with the DSP/BIOS 5 SEM module.

In the C code, the Semaphore application makes a call to the Semaphore_post() and Semaphore_pend() APIs.

Configuration Script Addition

```
var Sem = xdc.useModule('ti.sysbios.knl.Semaphore');  
Sem.supportsEvents = false;  
Program.global.sem0 = Sem.create(0);
```

C Code Addition

```
Semaphore_post(sem0);  
Semaphore_pend(sem0, BIOS_WAIT_FOREVER);
```

D.4.9 Semaphore Object Application

The Semaphore Object Application configuration script creates an additional Semaphore instance to illustrate the size impact of each new Semaphore instance.

Configuration Script Addition

```
Program.global.sem1 = Sem.create(0);
```

D.4.10 Memory Application

The Memory Application configuration script configures the default heap used for memory allocations. It creates a HeapMem instance to manage a 4 KB heap, places the heap into its own section in memory, then assigns the HeapMem instance as the default heap to use for Memory.

In the C code, the Memory application makes calls to the Memory_alloc() and Memory_free() APIs. It allocates a block from the default heap by passing NULL as the first parameter to Memory_alloc(), then frees the block back to the default heap by again passing NULL as the first parameter to Memory_free().

Configuration Script Addition

```
var mem = xdc.useModule('xdc.runtime.Memory');

var HeapMem =
    xdc.useModule('ti.sysbios.heaps.HeapMem');
var heap0 = HeapMem.create();
heap0.sectionName = "myHeap";
Program.sectMap["myHeap"] =
    Program.platform.dataMemory;
heap0.size = 0x1000;

mem.defaultHeapInstance = heap0;
```

C Code Addition

```
Ptr *buf;
buf = Memory_alloc(NULL, 128, 0, NULL);
Memory_free(NULL, buf, 128);
```

D.5 Dynamic Module Application Sizes

The following application demonstrate the size effects of creating object dynamically (in the C code).

D.5.1 Dynamic Task Application

The Dynamic Task Application demonstrates the size impact of dynamically (in the C code) creating and deleting a Task instance. This application comes after the Memory application because it must use the Memory module to allocate space for the new Task instance.

C Code Addition

```
Task_Handle task;  
task = Task_create((Task_FuncPtr)main, NULL, NULL);  
Task_delete(&task);
```

D.5.2 Dynamic Semaphore Application

The Dynamic Semaphore Application demonstrates the size impact of dynamically (in the C code) creating and deleting a Semaphore instance. This application comes after the Memory application because it must use the Memory module to allocate space for the new Semaphore instance.

C Code Addition

```
Semaphore_Handle sem;  
sem = Semaphore_create(1, NULL, NULL);  
Semaphore_delete(&sem);
```

D.6 Timing Application Size

The timing application is the application used to generate the timing benchmarks for SYS/BIOS 6 (see Appendix C). This application leverages all of the key components of the operating system in a meaningful way, and does not utilize any of the size-reducing measures employed in the base configuration of the size benchmarks. Therefore, this is the largest application provided as a benchmark.

Minimizing the Application Footprint

This appendix describes how to minimize the size of a SYS/BIOS application.

Topic	Page
E.1 Overview.....	E-2
E.2 Reducing Data Size	E-2
E.3 Reducing Code Size	E-4
E.4 Basic Size Benchmark Configuration Script.....	E-7

E.1 Overview

This section provides tips and suggestions for minimizing the memory requirements of a SYS/BIOS-based application. This is accomplished by disabling features of the operating system that are enabled by default and by reducing the size of certain buffers in the system.

All of the tips described here are applied to the base configuration for the size benchmarks. The final section of this chapter presents the configuration script used for the base size benchmark.

The actual size benchmark data is included in the SYS/BIOS 6 installation in the `ti.sysbios.benchmarks` package (that is, in the `BIOS_INSTALL_DIR\packages\ti\sysbios\benchmarks` directory). There is a separate HTML file for each target. For example, the 'C64x sizing information can be found in the `c6400Sizing.html` file.

The following sections simply describe different configuration options and their effect on reducing the application size. For further details on the impact of these settings, refer to the documentation for the relevant modules.

Because the code and data sections are often placed in separate memory segments, it may be more important to just reduce either code size data size. Therefore the suggestions are divided based on whether they reduce code or data size. In general, it is easier to reduce data size than code size.

E.2 Reducing Data Size

E.2.1 Removing the malloc Heap

Calls to `malloc` are satisfied by a separate heap, whose size is configurable. The following code minimizes the size of this heap. (Some targets do not support a heap size of 0, so this command sets it to 1.)

```
Program.heap = 0x1;
```

The `Program` variable is automatically available to all scripts. It defines the "root" of the configuration object model. It comes from the `xdc.cfg.Program` module, and is implicitly initialized as follows:

```
var Program = xdc.useModule('xdc.cfg.Program');
```

E.2.2 Reducing Space for Arguments to main()

A special section in memory is created to store any arguments to the main() function of the application. The size of this section is configurable, and can be reduced depending on the application's needs.

```
Program.argSize = 0x4;
```

E.2.3 Reducing the Size of Stacks

See Section 2.4.3 for information about system stack size requirements and Section 2.5.3 for information about task stack size requirements.

The size of the System stack, which is used as the stack for interrupt service routines (Hwis and Swis), is configurable, and can be reduced depending on the application's needs.

```
Program.stack = 0x400;
```

Likewise, the size of each Task stack is individually configurable, and can be reduced depending on the application's needs. See Section 2.5.3 for information about task stack sizes.

```
var tskParams = new Task.Params;  
tskParams.stackSize = 512;  
var task0 = Task.create('&task0Fxn', tskParams);
```

You can configure the size of the Idle task stack as follows:

```
Task.idleTaskStackSize = 512;
```

E.2.4 Disabling Named Modules

The space used to store module name strings can be reclaimed with the following configuration setting:

```
var Defaults = xdc.useModule('xdc.runtime.Defaults');  
Defaults.common$.namedModule = false;
```

E.2.5 Leaving Text Strings Off the Target

By default, all of the text strings in the system, such as module and instance names and error strings, are loaded into the target's memory. These strings can be left out of the application using the following settings.

```
var Text = xdc.useModule('xdc.runtime.Text');
Text.isLoading = false;
```

E.2.6 Disabling the Module Function Table

Modules that inherit from an interface (such as GateHwi, which inherits from IGate) by default have a generated function table that is used in supporting abstract handles for instances. For example, an API takes a handle to an IGate as one of its parameters. Because the type of the gate is abstract, it must use a function table to access the module functions for that gate. Likewise, several Memory module APIs expect an IHeap Handle as a parameter.

If the instances of one of these modules are never used in an abstract way, however, then the function table for the module is unnecessary and can be removed. For example, if none of the GateHwi instances in a system are ever cast to IGate instances, then the GateHwi function table can be disabled as follows.

```
var GateHwi = xdc.useModule('ti.sysbios.gates.GateHwi');
GateHwi.common$.fxntab = false;
```

It is generally not safe to set the common\$.fxntab property to false for Heap implementation modules, because access to their function table may be needed when internal calls to Memory APIs by the Heap implementation use abstract handles.

E.2.7 Reduce the Number of atexit Handlers

By default, up to 8 System_atexit() handlers can be specified that will be executed when the system is exiting. You can save data space by reducing the number of handlers that can be set at runtime to the number you are actually intending to use. For example:

```
System.maxAtexitHandlers = 0;
```

E.3 Reducing Code Size

E.3.1 Disabling Logging

Logging can be disabled with the following configuration settings:

```
var Defaults = xdc.useModule('xdc.runtime.Defaults');
var Diags = xdc.useModule('xdc.runtimg.Diags');
Defaults.common$.diags_ASSERT = Diags.ALWAYS_OFF;
```

E.3.2 Setting Memory Policies

The Memory module supports different “memory policies” for creating and deleting objects. If all of the objects in an application can be statically created in the configuration script, then all of the code associated with dynamically creating instances of modules can be left out of the application. This is referred to as a static memory policy.

```
var Defaults = xdc.useModule('xdc.runtime.Defaults');
var Types = xdc.useModule('xdc.runtime.Types');
Defaults.common$.memoryPolicy = Types.STATIC_POLICY;
```

E.3.3 Disabling Core Features

Some of the core features of SYS/BIOS can be enabled or disabled as needed. These include the Swi, Clock, and Task modules.

```
var BIOS = xdc.useModule('ti.sysbios.BIOS');
BIOS.swiEnabled = false;
BIOS.clockEnabled = false;
BIOS.taskEnabled = false;
```

Applications typically enable at least one of the Swi and Task handlers. Some applications may not need to use both Swi and Task, and can disable the unused thread type.

E.3.4 Eliminating printf()

There is no way to explicitly remove printf from the application. However, the printf code and related data structures are not included if the application is free of references to System_printf(). This requires two things:

- ❑ The application code cannot contain any calls to System_printf().
- ❑ The following configuration settings need to be made to SYS/BIOS:

```
var System = xdc.useModule('xdc.runtime.System');
var SysMin = xdc.useModule('xdc.runtime.SysMin');
SysMin.bufSize = 0;
SysMin.flushAtExit = false;
System.SupportProxy = SysMin;
```

```
//Remove Error_raiseHook, which brings System_printf
var Error = xdc.useModule('xdc.runtime.Error');
Error.raiseHook = null;
```

See the module documentation for details. Essentially, these settings will eliminate all references to the printf code.

E.3.5 Disabling RTS Thread Protection

If an application does not require the RTS library to be thread safe, it can specify to not use any Gate module in the RTS library. This can prevent the application from bringing in another type of Gate module.

```
var BIOS = xdc.useModule('ti.sysbios.BIOS');  
BIOS.rtsGateType = BIOS.NoLocking;
```

E.3.6 Disable Task Stack Overrun Checking

If you are not concerned that any of your Task instances will overrun their stacks, you can disable the checks that make sure the top of the stack retains its initial value. This saves on code space. See Section 2.5.3 for information about task stack sizes.

By default, stack checking is performed. Use these statements if you want to disable stack checking for all Tasks:

```
Task.checkStackFlag = false;  
Task.initStackFlag = false;
```

E.4 Basic Size Benchmark Configuration Script

The basic size benchmark configuration script puts together all of these concepts to create an application that is close to the smallest possible size of a SYS/BIOS application.

The values chosen for Program.stack and Program.argSize are chosen to match the settings used in generating the DSP/BIOS 5 benchmarks in order to support a fair comparison of the two systems.

Note that in a real-world application, you would want to enable at least either Swi or Task handlers so that your application could use some threads.

This configuration script works on any target.

```
var Defaults = xdc.useModule('xdc.runtime.Defaults');
var System = xdc.useModule('xdc.runtime.System');
var SysMin = xdc.useModule('xdc.runtime.SysMin');
var Error = xdc.useModule('xdc.runtime.Error');
var Text = xdc.useModule('xdc.runtime.Text');
var Types = xdc.useModule('xdc.runtime.Types');
var Diags = xdc.useModule('xdc.runtime.Diags');
var BIOS = xdc.useModule('ti.sysbios.BIOS');
var GateHwi = xdc.useModule('ti.sysbios.gates.GateHwi');
var HeapStd = xdc.useModule('xdc.runtime.HeapStd');
var Memory = xdc.useModule('xdc.runtime.Memory');

//Assumption: app needs SysMin at a minimum,
//but may not use printf, so buf can be zero.
SysMin.bufSize = 0;
SysMin.flushAtExit = false;
System.SupportProxy = SysMin;

//Get rid of Error_raiseHook which brings in
System_printf
Error.raiseHook = null;

//Heap used by malloc is set to zero length.
Program.heap = 0x1;

//arg and stack size made same as BIOS 5.00
Program.argSize = 0x4;
Program.stack = 0x400;

//Logger disabled for benchmarking
Defaults.common$.logger = null;
```

```
//Set isLoading for Text module
Text.isLoading = false;

//Set STATIC_POLICY
Defaults.common$.memoryPolicy = Types.STATIC_POLICY;
Defaults.common$.diags_ASSERT = Diags.ALWAYS_OFF;
Defaults.common$.namedModule = false;

BIOS.swiEnabled = false;
BIOS.clockEnabled = false;
BIOS.taskEnabled = false;
BIOS.rtsGateType = BIOS.NoLocking;

//App not using abstract GateHwi instances
GateHwi.common$.fxntab = false;
HeapStd.common$.fxntab = false;
```
